This collection of information is required by 37 CFR 1.51. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 8 hours to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Mail Stop Provisional Application, Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.

If you need assistance in completing the form, call 1-800-PTO-9199 and select option 2.

HIGHLY CRYSTALLINE CROSS-LINKED OXIDATION-RESISTANT POLYETHYLENE

5

FIELD OF THE INVENTION

The present invention relates to methods for making crystalline oxidation resistant cross-linked polymeric materials, including highly crystalline oxidation resistant cross-linked polymeric materials. Methods of crystallizing cross-linked polymeric materials under high pressure at elevated temperature and materials used therewith also are provided.

10

BACKGROUND OF THE INVENTION

Total joint arthroplasty for end-stage joint diseases most commonly involves a metal/polymer articular pair. Polyethylene, particularly ultrahigh molecular weight polyethylene (UHMWPE), has been and remains the material of choice for the load-bearing, articulating surface for this articular pair for more than four decades (Kurtz, *et al.*, *Biomaterials*, 1999, 20(18): p. 1659-1688). Despite high long-term success rates for such reconstructions, wear and fatigue damage of polyethylene limit the longevity of total joints. In total knees, implant failure is caused primarily by fatigue damage to the polyethylene components (Collier, *et al.*, *J. Arthroplasty*, 1996, 11(4): p. 377-389). One solution to prevent osteolysis in total hips is cross-linking, which markedly reduces polyethylene wear (Muratoglu, *et al.*, *J Arthroplasty*, 2001, 16(2): p. 149-160; Muratoglu, *et al.*, *Biomaterials*, 1999, 20(16): p. 1463-1470; McKellop, *et al.*, *J Orthop Res*, 1999, 17(2): p. 157-167).

20

Increased crosslink density in polymeric material is desired in bearing surface applications for joint arthroplasty because it significantly increases wear resistance. Oxidation resistant cross-linked polymeric material, such as UHMWPE, is desired in medical devices because it significantly increases the wear resistance of the devices. A method of cross-linking is by exposing the UHMWPE to ionizing radiation. However, cross-linking also reduces the fatigue strength of polyethylene, therefore limiting the use of highly cross-linked polyethylenes in total knees where the components are subjected to

25

30

cyclic loading accompanied by high stresses. Ionizing radiation, in addition to cross-linking, also will generate residual free radicals, which are the precursors of oxidation-induced embrittlement. This is known to adversely affect *in vivo* device performance. Therefore, it is desirable to reduce the concentration of residual free radicals, preferably to undetectable levels, following irradiation to avoid long-term oxidation.

One way of substantially reducing the concentration of residual free radicals in irradiated UHMWPE is to heat the irradiated UHMWPE to above its melting temperature (for example, about 137°C-140°C). Melting frees or eliminates the crystalline structure, where the residual free radicals are believed to be trapped. This increase in the free radical mobility facilitates the recombination reactions, through which the residual free radical concentration can be markedly reduced. This technique, while effective at recombining the residual free radicals, has been shown to decrease the final crystallinity of the material. This loss of crystallinity will reduce the modulus of the UHMWPE. Yet for high stress applications, such as unicompartmental knee designs, thin polyethylene tibial knee inserts, low conformity articulations, *etc.*, high modulus is desired to minimize creep.

Cross-linking by irradiation decreases the fatigue strength of UHMWPE. In addition, post-irradiation melting further decreases the fatigue strength of the UHMWPE. Radiation and melting also decrease the yield strength, ultimate tensile strength, toughness and elongation at break of UHMWPE.

Melting in combination with irradiation creates cross-links and facilitates recombination of the residual free radicals trapped mostly in the crystalline regions, which otherwise would cause oxidative embrittlement upon reactions with oxygen. Both cross-linking and melting, however, decrease the crystallinity of UHMWPE. Cross-linking and decrease in the crystallinity is thought to be the reason for decrease in fatigue strength, yield strength, ultimate tensile strength, toughness and elongation at break. Some or all of these changes in properties limit the use of low wear highly cross-linked UHMWPE to low stress applications. Therefore, a cross-linked UHMWPE with higher crystallinity is desirable for low wear and high fatigue resistance for high stress application that require low wear.

It is, therefore, desirable to reduce the irradiation-created residual free radical concentration in cross-linked UHMWPE without reducing crystallinity, so as to achieve high fatigue resistance for high stress application that require low wear. Alternative

methods to melting can be used to prevent the long-term oxidation of irradiated UHMWPE to preserve higher levels of crystallinity and fatigue strength.

The effect of crystallinity on the fatigue strength of conventional UHMWPE is known. Investigators increased the crystallinity of unirradiated UHMWPE by high-pressure crystallization, which increased the fatigue crack propagation resistance of unirradiated UHMWPE by about 25% (Baker *et al.*, *Polymer*, 2000, 41(2): p. 795-808). Others found that under high pressures (2,000-7,000 bars) and high temperatures (>200°C), polyethylene grows extended chain crystals and achieves a higher crystallinity level (Wunderlich *et al.*, *Journal of Polymer Science Part A-2: Polymer Physics*, 1969, 7(12): p. 2043-2050). However, high-pressure crystallization of highly cross-linked UHMWPE has not been previously attempted or discussed. Also, the crystallization behavior of highly cross-linked polyethylene at high pressures has not been determined.

Polyethylene undergoes a phase transformation at elevated temperatures and pressures from the orthorhombic to the hexagonal crystalline phase. The hexagonal phase can grow extended chain crystals and result in higher crystallinity in polyethylene. This is believed to be a consequence of less hindered crystallization kinetics in the hexagonal phase compared with the orthorhombic phase. One could further reduce the hindrance on the crystallization kinetics by introducing a plasticizing or a nucleating agent into the polyethylene prior to high-pressure crystallization. The polyethylene can be doped with a plasticizing agent, for example, α -tocopherol or vitamin-E, prior to high-pressure crystallization. The doping can be achieved either by blending the polyethylene resin powder with the plasticizing agent and consolidating the blend or by diffusing the plasticizing agent into the consolidated polyethylene. Various processes of doping can be employed as described in US Application Serial No. 10/757,551, filed January 15, 2004, and PCT/US/04/00857, filed January 15, 2004, the entirety of which are hereby incorporated by reference.

SUMMARY OF THE INVENTION

The present invention relates generally to methods of making crystalline oxidation-resistant cross-linked polymeric material, preferably the cross-linked material has higher crystallinity than obtainable with previous methodologies. More specifically, the invention

relates to methods of radiation cross-linking highly crystalline UHMWPE and subsequently treating the UHMWPE to increase its oxidation resistance. Also the invention relates to methods of crystallizing cross-linked ultra-high molecular weight polyethylene (UHMWPE) under high pressure at elevated temperature in the hexagonal phase, whereby
5 extended chain crystals are present and high crystallinity are achieved, followed by treating the UHMWPE to increase its oxidation resistance. Also the invention relates to methods of crystallizing cross-linked ultra-high molecular weight polyethylene (UHMWPE) under high pressure at elevated temperature in the hexagonal phase where high crystallinity is achieved and the residual free radical population is reduced.

10 The process comprises steps of crystallizing polyethylene under high pressure at elevated temperature, irradiating at different temperatures below the melt to control the amount of amorphous, folded and extended chain crystals during cross-linking. This invention also relates to processes to increase oxidation resistance where an antioxidant is incorporated into polyethylene, or a cross-linked polyethylene is mechanically deformed
15 and annealed, or a high pressure and high temperatures are applied to the cross-linked polyethylene. The processes can be used separately or together in various orders in accordance with the teachings herein and the skill in the art.

One aspect of the invention provides methods of making highly crystalline cross-linked polymeric material comprising: a) heating a polymeric material to a temperature
20 above the melt; b) pressurizing the heated polymeric material, preferably under a pressure of at least about 150 MPa; c) holding at this pressure; d) cooling the heated polymeric material to about room temperature; e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; and f) irradiating the highly crystalline polymeric material at a temperature below the melt with ionizing radiation,
25 thereby forming a highly crystalline cross-linked polymeric material.

In another aspect, the invention provides methods of making a oxidation-resistant cross-linked polymeric material comprising: a) heating a polymeric material to a temperature above the melt; b) pressurizing the heated polymeric material under at least about 150 MPa; c) holding at this pressure; d) cooling the heated polymeric material to
30 about room temperature; e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; f) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation, thereby forming a

highly crystalline cross-linked polymeric material; g) heating the highly crystalline cross-linked polymeric material to a temperature above the melt; h) pressurizing the heated polymeric material under at least about 150 MPa; i) holding at this pressure; j) cooling the heated polymeric material to about room temperature; and k) releasing the pressure to an atmospheric pressure level, thereby forming an oxidation-resistant cross-linked polymeric material.

In another aspect, invention provides methods of making highly crystalline cross-linked polymeric material comprising: a) pressurizing a polymeric material under at least about 150 MPa; b) heating the pressurized polymeric material to a temperature below the melt of the pressurized polymeric material, such as below 140°C; c) holding at this pressure; d) cooling the heated polymeric material to about room temperature; e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; and f) irradiating the highly crystalline polymeric material at a temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked polymeric material.

In another aspect, the invention provides methods of making oxidation-resistant cross-linked polymeric material comprising: a) pressurizing a polymeric material under at least about 150 MPa; b) heating the pressurized polymeric material to a temperature below the melt of the pressurized polymeric material, such as below 140°C; c) holding at this pressure; d) cooling the heated polymeric material to about room temperature; e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; f) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked polymeric material; g) heating the highly crystalline cross-linked polymeric material to a temperature above the melt; h) pressurizing the heated polymeric material under at least about 150 MPa; i) holding at this pressure; j) cooling the heated polymeric material to about room temperature; k) releasing the pressure to an atmospheric pressure level, thereby forming an oxidation-resistant cross-linked polymeric material.

In another aspect, the oxidation-resistant highly crystalline cross-linked polymeric material is machined, thereby forming a medical implant. In another aspect, the oxidation-resistant highly crystalline cross-linked medical implant is packaged and sterilized by

ionizing radiation or gas sterilization, thereby forming a sterile oxidation resistant highly crystalline cross-linked medical implant.

In one aspect, the invention provides methods of making a cross-linked highly crystalline blend of polymer and additive comprising: a) blending polymeric material with an additive; b) consolidating the blend; c) pressurizing the blend under at least about 150 MPa; d) heating the pressurized the blend to a temperature of above 100°C to below the melt of the pressurized blend; e) holding at this pressure; f) cooling the heated the blend to about room temperature; g) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; h) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked blend of polymer and additive.

In one aspect, the invention provides methods of making a cross-linked highly crystalline blend of polymer and additive comprising: a) blending polymeric material with an additive; b) consolidating the blend; c) heating the blend to a temperature above the melting point of the blend; d) pressurizing the blend under at least about 150 MPa; e) holding at this pressure; f) cooling the heated the blend to about room temperature; g) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; h) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation, thereby forming an oxidation resistant highly crystalline cross-linked blend of polymer and additive.

In one aspect, the invention provides methods of making an oxidation resistant cross-linked highly crystalline blend of polymer and additive comprising: a) blending polymeric material with an additive; b) consolidating the blend; c) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation; d) heating the cross-linked blend to a temperature above the melting point of the blend; e) pressurizing the cross-linked blend under at least about 150 MPa; f) holding at this pressure; g) cooling the heated the cross-linked blend to about room temperature; h) releasing the pressure to an atmospheric pressure level, thereby forming a an oxidation resistant highly crystalline cross-linked blend of polymer and additive.

In one aspect, the invention provides methods of making a cross-linked highly crystalline blend of polymer and additive comprising: a) blending polymeric material with an additive; b) consolidating the blend; c) heating the blend to a temperature above the

melting point of the blend; d) pressurizing the blend under at least about 150 MPa; e) holding at this pressure; f) cooling the heated the blend to about room temperature; g) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; h) machining the polymeric material thereby forming a medical
5 implant; and i) irradiating the medical implant at temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked medical implant.

One aspect of the invention provides methods of making a cross-linked highly crystalline blend of polymer and additive comprising: a) blending polymeric material with an additive; b) consolidating the blend; c) pressurizing the blend under at least about 150
10 MPa; d) heating the pressurized the blend to a temperature of above 100°C to below the melt of the pressurized blend; e) holding at this pressure; f) cooling the heated the blend to about room temperature; g) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; h) machining the polymeric material thereby forming a medical implant; and i) irradiating the medical implant at temperature
15 below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked medical implant.

In one aspect, invention provides methods of making an oxidation resistant cross-linked highly crystalline blend of polymer and plasticizing agent comprising: a) blending polymeric material with an additive; b) consolidating the blend; c) irradiating the highly
20 crystalline polymeric material at temperature below the melt with ionizing radiation; d) heating the cross-linked blend to a temperature above the melting point of the blend; e) pressurizing the cross-linked blend under at least about 150 MPa; f) holding at this pressure; g) cooling the heated the cross-linked blend to about room temperature; h) releasing the pressure to an atmospheric pressure level, thereby forming a oxidation
25 resistant cross-linked highly crystalline cross-linked blend of polymer and additive; and i) machining the polymeric material thereby forming an oxidation resistant highly crystalline cross-linked medical implant.

In another aspect, the highly crystalline cross-linked blend of polymer and additive is machined, thereby forming a medical implant. In another aspect, the highly crystalline
30 cross-linked medical implant is packaged and sterilized by ionizing radiation or gas sterilization, thereby forming a sterile highly crystalline cross-linked medical implant.

In another aspect, the invention provides a method of making highly crystalline blend of polymer with an additive comprising a plasticizing agent or a nucleating agent as additive.

5 In another aspect, the invention provides a method of making oxidation resistant highly cross-linked blend of polymer comprising plasticizing the polymer with an additive like an antioxidant plasticizing agent, such as vitamin E.

In another aspect, the invention provides methods of making oxidation-resistant highly crystalline cross-linked polymeric material further comprising doping the highly crystalline cross-linked polymeric material with an antioxidant by diffusion, thereby
10 forming an antioxidant-doped highly crystalline cross-linked polymeric material.

In another aspect, the invention provides methods of making highly crystalline cross-linked polymeric material further comprising: a) machining the highly crystalline cross-linked polymeric material, thereby forming a medical implant; and b) doping the medical implant with an antioxidant by diffusion, thereby forming an antioxidant-doped
15 highly crystalline cross-linked medical implant.

In another aspect, the invention provides methods of making highly crystalline cross-linked polymeric material further comprising: a) doping the highly crystalline cross-linked polymeric material with an antioxidant by diffusion, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material; and b) machining the antioxidant-doped highly crystalline cross-linked polymeric material, thereby forming an antioxidant-doped highly crystalline cross-linked medical implant.
20

In one aspect, the antioxidant-doped highly crystalline cross-linked medical implant is packaged and sterilized by ionizing radiation or gas sterilization, thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

25 In another aspect, the invention provides methods of making highly crystalline cross-linked polymeric material further comprising: a) pressurizing the polymeric material under at least about 150 MPa; b) heating the pressurized polymeric material to a temperature of above 140°C to below the melt of the pressurized polymeric material; c) cooling the heated polymeric material to about room temperature; d) releasing the pressure to an atmospheric pressure level; e) doping the polymeric material with an antioxidant by
30 diffusion, thereby forming an antioxidant-doped polymeric material; and f) irradiating the

antioxidant-doped polymeric material at temperature below the melt with ionizing radiation, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material.

In another aspect, the invention provides methods of making a highly crystalline cross-linked polymeric material further comprising: a) pressurizing the polymeric material under at least about 150 MPa; b) heating the pressurized polymeric material to a temperature of above 140°C to below the melt of the pressurized polymeric material; c) cooling the heated polymeric material to about room temperature; d) releasing the pressure to an atmospheric pressure level; e) machining the highly crystalline polymeric material, thereby forming a medical implant; and f) doping the medical implant with an antioxidant by diffusion, thereby forming an antioxidant-doped medical implant; and g) irradiating the antioxidant-doped medical implant at temperature below the melt with ionizing radiation, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material.

In another aspect, the invention provides a method of making highly crystalline cross-linked polymeric material further comprising: a) heating the polymeric material to a temperature above the melt; b) pressurizing the heated polymeric material under at least about 150 MPa; c) cooling the heated polymeric material to about room temperature; d) releasing the pressure to an atmospheric pressure level; e) doping the polymeric material with an antioxidant by diffusion, thereby forming an antioxidant-doped polymeric material; and f) irradiating the antioxidant-doped polymeric material at temperature below the melt with ionizing radiation, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material.

In another aspect, the invention provides methods of making highly crystalline cross-linked polymeric material comprising: a) heating the polymeric material to a temperature above the melt; b) pressurizing the heated polymeric material under at least about 150 MPa; c) cooling the heated polymeric material to about room temperature; d) releasing the pressure to an atmospheric pressure level; e) machining the highly crystalline polymeric material, thereby forming a medical implant; f) doping the medical implant with an antioxidant by diffusion, thereby forming an antioxidant-doped medical implant; and g) irradiating the antioxidant-doped medical implant at temperature below the melt with ionizing radiation, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material.

In another aspect, the antioxidant-doped highly crystalline cross-linked polymeric material is machined, thereby forming a medical implant.

In another aspect, the antioxidant-doped highly crystalline cross-linked medical implant is washed, packaged and sterilized by ionizing radiation or gas sterilization, thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

In one aspect, before packaging and sterilization, the antioxidant-doped highly crystalline cross-linked medical implant is washed in an industrial washing machine with detergent. In another aspect, before packaging and sterilization, the antioxidant-doped highly crystalline cross-linked medical implant is washed by soaking in a solvent, such as ethanol.

In another aspect, the antioxidant-doped highly crystalline cross-linked polymeric material is washed, then machined, thereby forming a medical implant.

In another aspect, the antioxidant-doped highly crystalline cross-linked medical implant is packaged and sterilized by ionizing radiation or gas sterilization, thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

In another aspect, the antioxidant-doped highly crystalline cross-linked medical implant is packaged and sterilized by gas sterilization, thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

In another aspect, the highly crystalline and antioxidant-doped medical implant is packaged and irradiated with ionizing radiation to a radiation dose level of above 25 kGy to cross-link and sterilize the medical implant. Preferably the radiation dose level is above 75 kGy and more preferably above 100 kGy.

In one aspect, the polymeric material is heated to a temperature above the melting point of the pressurized polymeric material, for example, at 150°C, 180°C, 225°C, 300°C, or 320°C.

In another, aspect, the invention provides a method of making oxidation resistant highly crystalline cross-linked polymeric material comprising: a) heating a polymeric material to a temperature above the melt; b) pressurizing the heated polymeric material under at least about 150 MPa; c) holding at this pressure; d) cooling the heated polymeric

material to about room temperature; e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; f) irradiating the highly crystalline polymeric material at a temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked polymeric material; g) doping with an antioxidant, such as vitamin-E, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material; h) mechanically deforming the antioxidant-doped highly crystalline cross-linked polymeric material below its melting point; and i) annealing the mechanically deformed antioxidant-doped polymeric material at a temperature below the melting point.

10 In another aspect, the invention provides a method of making an oxidation resistant highly crystalline cross-linked polymeric material comprising: a) pressurizing a polymeric material under at least about 150 MPa; b) heating the pressurized polymeric material to a temperature above 140°C to below the melt of the pressurized polymeric material; c) holding at this pressure; d) cooling the heated polymeric material to about room
15 temperature; e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; f) irradiating the highly crystalline polymeric material at a temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked polymeric material; g) doping with an antioxidant, such as vitamin-E, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material; h) mechanically deforming the antioxidant-doped highly crystalline cross-linked polymeric material below its melting point; and i) annealing the mechanically deformed antioxidant-doped polymeric material at a temperature below the melting point.

In another aspect, the invention provides methods of making an oxidation resistant cross-linked highly crystalline blend of polymer and additive comprising: a) blending
25 polymeric material with an additive; b) consolidating the blend; c) heating the blend to a temperature above the melting point of the blend; d) pressurizing the blend under at least about 150 MPa; e) holding at this pressure; f) cooling the heated the blend to about room temperature; g) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; h) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation, thereby forming an
30 oxidation resistant highly crystalline cross-linked blend of polymer and additive; i) doping with an antioxidant, such as vitamin-E, thereby forming an antioxidant-doped highly

crystalline cross-linked blend; j) mechanically deforming the antioxidant-doped highly crystalline cross-linked blend below its melting point; and k) annealing the mechanically deformed antioxidant-doped blend at a temperature below the melting point.

In another aspect, the invention provides methods of making an oxidation resistant cross-linked highly crystalline blend of polymer and additive comprising: a) blending
5 polymeric material with an additive; b) consolidating the blend; c) pressurizing the blend under at least about 150 MPa; d) heating the pressurized the blend to a temperature between above 100°C and below the melting point of the pressurized blend; e) holding at this pressure; f) cooling the heated the blend to about room temperature; g) releasing the
10 pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; h) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked blend of polymer and additive; i) doping with an antioxidant, such as vitamin-E, thereby forming an antioxidant-doped highly crystalline cross-linked blend; j) mechanically deforming the
15 antioxidant-doped highly crystalline cross-linked blend below its melting point; and k) annealing the mechanically deformed antioxidant-doped blend at a temperature below the melting point.

In another aspect, the highly crystalline polymeric material is irradiated at a temperature between about room temperature and about 90°C, or at a temperature between
20 about 90°C and the peak melting point of the highly crystalline polymeric material.

In another aspect, the irradiated polymeric material is annealed at a temperature below the melting point of the polymeric material, for example, a temperature between about 90°C and peak melting point of the irradiated polymeric material.

In another aspect, the polymeric material is pressurized to above about 150 MPa, for
25 example, about 200 MPa, 300 MPa, 320 MPa, or 400 MPa.

Yet in another aspect, the invention provides medical implants comprising the highly crystalline cross-linked and antioxidant-doped highly crystalline cross-linked polymeric material and highly crystalline cross-linked polymer blend with an additive made as described herein. In another aspect, the polymeric material is compression molded
30 to another piece or a medical implant, thereby forming an interface or an interlocked hybrid material. The medical implants, according to an aspect of the invention, comprises medical

devices including acetabular liner, shoulder glenoid, patellar component, finger joint component, ankle joint component, elbow joint component, wrist joint component, toe joint component, bipolar hip replacements, tibial knee insert, tibial knee inserts with reinforcing metallic and polyethylene posts, intervertebral discs, sutures, tendons, heart valves, stents, vascular grafts.

Unless otherwise defined, all technical and scientific terms used herein in their various grammatical forms have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although methods and materials similar to those described herein can be used in the practice or testing of the present invention, the preferred methods and materials are described below. In case of conflict, the present specification, including definitions, will control. In addition, the materials, methods, and examples are illustrative only and are not limiting.

Further features, objects, and advantages of the present invention are apparent in the claims and the detailed description that follows. It should be understood, however, that the detailed description and the specific examples, while indicating preferred aspects of the invention, are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed description.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 shows schematically the high-pressure crystallization process and phases of polyethylene under various temperature and pressure conditions.

Figure 2 schematically shows various steps and methods of making highly crystalline oxidation resistant cross-linked polymeric material.

Figure 3 shows α -tocopherol profile in UHMWPE doped for 96 hours and annealed for 96 hours at 132°C.

Figure 4 depicts DSC thermograms of a conventional and a high pressure crystallized conventional unirradiated polyethylene.

Figure 5 shows an optical micrograph of a cylindrical cross-section of a high pressure crystallized conventional polyethylene.

Figure 6 depicts DSC thermograms of a warm irradiated/melted and a high pressure crystallized warm irradiated/melted polyethylene.

Figure 7A, 7B, and 7C depict scanning electron micrographs of (a) transparent (7A), (b) opaque (7B), and (c) transition between opaque and transparent (7C), respectively, sections of high pressure crystallized conventional UHMWPE.

Figure 8 shows crystallinity of various high pressure crystallized, irradiated, and control UHMWPEs.

Figure 9 shows Oxidation Index as a function of distance away from the surface of accelerated aged 100-kGy irradiated, α -T-92 and α -T-127 samples. The curves represent splined averages of three test samples.

Figure 10 shows average maximum oxidation levels for unaged and aged high pressure crystallized, 100-kGy e-beam irradiated, and α -tocopherol doped UHMWPE. Doping was done in air for 16 hours at room temperature and at 100°C. Corresponding thermal controls also were kept at room temperature and at 100°C, respectively, for 16 hours in air without doping.

Figure 11 depicts splined averages (n=3) of the oxidation profiles of high pressure crystallized, 100-kGy irradiated, α -tocopherol doped, and accelerated aged UHMWPEs.

Figure 12 indicates Pin-on-Disk (POD) wear rates of unaged and aged Vitamin E doped and undoped samples.

Figure 13 shows the wear rates of unaged, just accelerated aged and ethanol extracted and accelerated aged α -T-92 and α -T-127.

Figure 14 shows the oxidation profiles of accelerated aged 111-kGy irradiated control and 111-kGy irradiated and α -tocopherol-doped and cleaned UHMWPE.

DETAILED DESCRIPTION OF THE INVENTION

The invention provides methods of making highly crystalline oxidation resistant cross-linked polymeric material, medical implants made thereof, which comprise medical devices, including permanent and non-permanent medical devices. The invention pertains to methods of crystallizing polyethylene, such as UHMWPE, under high pressure at

elevated temperature, irradiating at different temperatures, doping the cross-linked polyethylene with an antioxidant. The invention also pertains to methods of blending polyethylene with an additive, such as Vitamin E, crystallizing the blend, irradiating at different temperatures including cold irradiation below the melt and subsequent mechanical annealing.

Polyethylene is a semi-crystalline material (55-60%) and contains folded chain crystals when crystallized from the melt under ambient pressures. The majority of the crystals are in the orthorhombic phase with lattice dimensions of 7.42, 4.95, and 2.55 Å for a, b and c dimensions, respectively. The unit cell axes are at 90° to each other. Deformation gives rise to the monoclinic phase with lattice dimensions of 8.09, 4.79, and 2.55 Å. In the hexagonal phase, which is only encountered at pressures in excess of 300 MPa (see Figure 1, for example), the unit cell dimensions become 8.42, 4.56, and <2.55 Å. In this phase, the individual chain stems are rotated at random phase angles with respect to each other allowing for chains to slide past each other to form a densely packed structure. The crystals in this phase are termed the 'Extended Chain Crystals' (ECC) because the dense packing allows the crystals to grow to a larger extent than folded chain crystals.

It is known that the crystallinity of uncross-linked UHMWPE can be increased by high pressure and high temperature crystallization. For instance, when crystallized uncross-linked UHMWPE at pressures above 300 MPa and 180°C to obtain the hexagonal phase transition, the peak melting point of the crystals, as determined by differential scanning calorimetry (DSC), shifted to higher temperatures and the overall crystallinity increased. Uncross-linked high pressure crystallized polyethylene with high crystallinity appeared to have higher fatigue resistance as a function of increasing crystallinity (see Baker *et al.*, *Polymer*, 2000, 41(2): p. 795-808). Therefore, an object of the invention was to achieve a highly cross-linked (25-100 kGy) polyethylene with high crystallinity (>51%) and good oxidation resistance.

High toughness and high fatigue strength of polymers are attributed to energy absorbing mechanisms such as cavitation and plastic deformation. The major energy absorbing mechanism in polyethylene is the plastic deformation of the crystalline domains (crystal plasticity), which depends on ductility and crystallinity. Cross-linking polyethylene with high dose levels of irradiation drastically reduces the mobility of the chains, hence reducing the overall ductility. Melting in the presence of cross-links limits the ability of the

chains to reorder and hence decreases the crystallinity of polyethylene. The combination of these two factors, namely reduced chain mobility and reduced crystallinity, reduces cross-linked and melted polyethylene's fatigue resistance.

According to the invention, highly crystalline cross-linked oxidation resistant polyethylene can be obtained following various processes and steps (see Figure 2, for example), as described below, for example:

1. High pressure crystallize unirradiated/uncross-linked polyethylene using either Route I or Route II:

A. Route I: Heat to the desired temperature, for example, above the melt; then pressurize; then hold pressure at about the same pressure, for one minute to a day or more, preferably about 0.5 hours to 12 hours, more preferably 1 to 6 hours; then release the pressure (pressure has to be released after cooling down to room temperature to avoid melting of the crystals achieved under high pressure).

B. Route II: Pressurize to the desired pressure; then heat to the desired temperature, for example, below the melt of pressurized polyethylene; then hold pressure at about the same pressure, for one minute to a day or more, preferably about 0.5 hours to 12 hours, more preferably 1 to 6 hours; then cool to room temperature; then release the pressure (pressure has to be released after cooling down to room temperature to avoid melting of the crystals achieved under high pressure).

2. Then irradiate the high-pressure crystallized (HPC) polyethylene using either cold or warm irradiation:

A. Cold Irradiation (CI): irradiate at between about room temperature and 90°C using either e-beam or gamma radiation. If the crystallinity of the HPC-polyethylene is too high, there may not be enough amorphous polyethylene available for cross-linking. Therefore, it may require higher than usual dose levels, that is the dose levels required for polyethylene crystallized without high-pressure (as described herein, for example, usual dose levels of 75 kGy or 100 kGy), to achieve a desired wear resistance or crosslink density.

B. Warm Irradiation (WI): irradiate at between about 90°C and the peak melting point of HPC-polyethylene, which is generally around 145°C. The temperature of

irradiation can be adjusted to achieve a desired extent of amorphous polyethylene during irradiation.

3. Then treat the irradiated HPC-polyethylene (I-HPC) by either one of the following methods or a combination thereof:

5 A. Repeat the high-pressure crystallization following Route I or Route II, as described above.

 B. Dope with an antioxidant, such as vitamin E, which can be done by various ways, for example,

 i. machine the final product, soak in vitamin-E or its solution at
10 between room temperature and boiling point of vitamin-E solution; then wash, package and sterilize with either gas plasma, ethylene oxide, or ionizing radiation, such as gamma either in air or in inert gas.

 ii. soak highly crystalline polymeric material in vitamin E or its
solution at between room temperature and boiling point of vitamin-E solution; machine
15 medical implant, then wash, package and irradiate packaged medical implant to cross-link and sterilize.

 C. Treat with a CIMA (Cold Irradiation and Mechanically Annealed) method, for example,

 i. heat to a temperature between 90°C and peak melting point of I-
20 HPC, deform under compression to a compression ratio of above 2.5, hold deformation and cool to room temperature, anneal at a temperature between 90°C and peak melting point of I-HPC, machine the final product, package and sterilize, preferably sterilize with ethylene oxide or gas plasma. CIMA methods can be applied as described in US Patent publication 20030149125 (US Application Serial No. 10/252,582), filed September 24, 2002, the
25 entirety of which is hereby incorporated by reference.

 An antioxidant, which is compatible with lipophilic polyethylene, blends well with and protects irradiated polyethylene against oxidation, at radiation doses as high as 100 kGy. Moreover, antioxidant was found not to interfere with cross-linking of polyethylene, when diffused after irradiation. Therefore, cross-linked polyethylene diffused with
30 antioxidant after irradiation showed wear rates comparable to contemporary cross-linked

and melted polyethylenes. Mechanical deformation at temperatures below the melt also is an alternative approach of removing residual free radicals from irradiated polyethylene without melting.

5 The present invention also provides methods of crystallizing a blend of polymer with an additive under a high pressure and high temperatures and irradiating thus formed highly crystalline blend to obtain a highly crystalline, cross-linked blend of polymer and the additive. The present invention also provides methods of crystallizing a blend of polymer with additive, which is also an antioxidant, under a high pressure and high temperatures and irradiating thus formed highly crystalline blend to obtain a highly
10 crystalline, cross-linked oxidation resistant blend of polymer and an additive, which is also an antioxidant.

The present invention also provides methods of improving the oxidation resistance of highly crystalline cross-linked UHMWPE without melting. Melting of the highly crystalline UHMWPE will eliminate the ECC and reduce the crystallinity of the polymer.
15 Therefore, the present invention provides the methods that use antioxidant or mechanical deformation below the melting point. According to the invention, improvement of oxidation resistance can be achieved either by doping with an antioxidant as described herein or by mechanical deformation methods. The mechanical deformation is used after irradiation to reduce the population of residual free radicals without melting the polymer,
20 for example, uniaxially compressing to a compression ratio of at least 2.0 below the melting point (for example, less than about 150°C) is utilized to reduce the residual free radical concentration. According to the invention, orientation and some of the thermal stresses that can persist following the mechanical deformation are reduced by further annealing at an elevated temperature below the melting point and cooling down. Following
25 annealing, it may be desirable to cool down the polyethylene at slow enough cooling rate (for example, at about 10°C/hour) so as to minimize thermal stresses.

As described herein, it is demonstrated that mechanical deformation can eliminate residual free radicals in a radiation cross-linked UHMWPE. The invention also provides that one can first deform UHMWPE to a new shape either at solid- or at molten-state, for
30 example, by compression. According to a process of the invention, mechanical deformation of UHMWPE when conducted at a molten-state, the polymer is crystallized under load to maintain the new deformed shape. Following the deformation step, the

deformed UHMWPE sample is irradiated at a temperature below the melting point to crosslink, which generates residual free radicals. To reduce or eliminate these free radicals, the irradiated polymer specimen is heated to a temperature below the melting point of the deformed and irradiated polyethylene (for example, up to about 150°C) to allow for the shape memory to partially recover the original shape. Generally, it is expected to recover about 80-90% of the original shape. During this recovery, the crystals undergo motion, which can help the free radical recombination and elimination. The above process is termed as a 'reverse-IBMA'. The reverse-IBMA (reverse-irradiation below the melt and mechanical annealing) technology can be a suitable process in terms of bringing the technology to large-scale production of UHMWPE-based medical devices.

In one aspect, the invention discloses medical implants, including permanent and non-permanent medical devices, comprising polymeric material having high crosslink density, high crystallinity, wear and oxidation resistance comparable with a highly cross-linked and melted polyethylene with fatigue resistance above highly cross-linked and melted polyethylene.

Medical implants, as disclosed herein can be obtained by various processes disclosed herein, for example, consolidating polymeric material; crystallizing the consolidated polymeric material under a high temperature, such as at above 150°C and at a high pressure, such as at above 150 MPa, subsequently, cooling down to room temperature followed by reducing the pressure to ambient, subsequently heating and holding the high pressure crystallized polymeric material at a certain temperature, such as at below 150°C, so as to achieve partly amorphous polyethylene; irradiating by ionizing radiation to a dose of above about 75 kGy, preferably about 100 kGy; more preferably about 150kGy; increasing the oxidation resistance by either doping with an antioxidant or decreasing the concentration of residual free radicals, for example, by mechanical deformation and annealing and/or crystallizing under high pressure and temperature.

Crystallization under high pressure can be done by first melting the polyethylene at low pressure, subsequently pressurizing to above 150 MPa, and cooling to room temperature; or by first pressurizing to above 150 MPa, then increasing the temperature until orthorhombic to hexagonal phase transition occurs, then cooling down and depressurizing.

The holding time in the melt, the holding time under pressure, the ultimate temperature and pressure and the cooling rate can be changed to obtain the highest crystallinity and a roughly equal amount of extended and folded chain crystals.

5 The temperature at which the folded chain crystals of the high pressure crystallized polyethylene are melted and the holding time at the temperature can be changed to obtain a desired ratio of extended to folded chain crystals and amorphous content.

Irradiation cross-links the high pressure crystallized polyethylene and provides wear resistance. Irradiation can be done at room temperature or at elevated temperatures below the melting point of polyethylene. Irradiation can be done in air, in vacuum, or in oxygen-
10 free environment, including inert gases such as nitrogen or noble gases. Irradiation can be done by using electron-beam, gamma irradiation, or x-ray irradiation.

The adverse oxidative effects of residual free radicals caused by ionizing radiation are reduced by diffusing an antioxidant such as α -tocopherol into high pressure crystallized, partially melted and cross-linked polyethylene. The antioxidant prevents oxidation of
15 irradiated materials. Doping of polyethylene by an antioxidant is performed as described herein.

The adverse oxidative effects of residual free radicals caused by ionizing radiation is reduced by using a blend of polymer and additive, which is also an antioxidant, such as α -tocopherol to high pressure crystallize and irradiate.

20 In another aspect, the residual free radicals caused by ionizing radiation are removed by mechanical annealing, where the polyethylene is heated to a temperature below the melting point (less than about 150°C), preferably 145°C, more preferably at about 140°C and deformed mechanically to provide mobility for the residual free radicals to recombine and stabilize.

25 In another aspect, the residual free radicals generated during ionizing radiation is removed by heating polyethylene to melt. Melting of the irradiated polyethylene is used as part of high-pressure crystallization subsequent to irradiation.

A high crystalline polyethylene can be made by a process comprising high-pressure crystallization of unirradiated polyethylene, followed by irradiation, and elimination of the
30 free radicals generated during the process, with minimum compromise in the crystallinity achieved.

According to one aspect of the invention, polyethylene is pressurized to above about 150 MPa, preferably to about 320 MPa, more preferably to above 320 MPa, heated to either about 180 or about 225°C, held at that temperature and that pressure, cooled to room temperature, reduced pressure to ambient, and irradiated at room temperature.

5 Subsequently, one of the following processes can be employed in order to improve oxidation resistance of the high pressure crystallized polyethylene: a) doping the high pressure crystallized polyethylene with an antioxidant, such as vitamin-E; or b) mechanically deforming the high pressure crystallized polyethylene below its melting point followed by annealing near its melting point, essentially applying any of the CIMA

10 methods, and c) heating to above the melting point, pressurizing to at least about 150 MPa, preferably to about 320 MPa, more preferably above 320 MPa, holding at this temperature and pressure, cooling to room temperature, reducing pressure to ambient.

A potential draw-back of irradiating a highly crystalline polyethylene at room temperature can be that the reduced concentration of amorphous phase, where cross-linking

15 primarily takes place, in a polyethylene with increased crystallinity can also reduce the concentration of crosslinks formed by irradiation. Therefore, it is preferable to irradiate polyethylene at an elevated temperature where the polymer is approximately 60% or less crystalline to increase the amorphous content. High pressure crystallized polyethylene exhibits two melting peaks, one at about 137°C and the other at above about 140°C. The

20 second peak is formed during high-pressure crystallization and represents extended chain crystals (larger ones). The following sequence of events is applied according to one aspect of the invention: Heated to a temperature below 140°C to melt some of the smaller crystals and also cross-linked the regions that contain smaller crystals; irradiated at this temperature (warm irradiation (WI)), then one of the following processes are employed in order to

25 improve oxidation resistance of the high pressure crystallized polyethylene:

a) doping the high-pressure crystallized polyethylene with an antioxidant, such as vitamin-E;

b) mechanically deforming the high-pressure crystallized polyethylene below its melting point followed by annealing near its melting point, essentially applying any of the

30 CIMA methods; and

c) melt by heating to above the melting point, then pressurizing to about 320 MPa, holding pressure and temperature about constant, cooling to room temperature, and

reducing pressure to ambient. The melting step of this process will eliminate the crystals; therefore, the process is followed by high-pressure crystallization to achieve a high level of crystallinity.

5 In one aspect of the invention, the doping of high pressure crystallized polyethylene can be carried out by diffusion of an antioxidant, for example, α -tocopherol, such as vitamin E. According to one aspect of the invention, diffusion of the antioxidant is accelerated by increasing the temperature and/or pressure.

 According to another aspect of the invention, an antioxidant is delivered in various
10 forms, including in a pure form, for example, as pure vitamin E, or dissolved in a solvent.

 According to another aspect of the invention, the diffusion rate of an antioxidant into the polyethylene is increased by increasing the concentration of the antioxidant solution, for example, a vitamin E solution.

 In accordance with another aspect of the invention, diffusion rate of an antioxidant
15 into the polyethylene is increased by swelling the high pressure crystallized polyethylene in a supercritical fluid, for example, in a supercritical CO₂, *i.e.*, the temperature being above the supercritical temperature, which is 31.3°C, and the pressure being above the supercritical pressure, which is 73.8 bar.

 In general, for example, in case of vitamin E, as the antioxidant, mixing the resin
20 powder, flakes, particles, or a mixture thereof, with vitamin E and consolidation thereafter result in changes in color of polymeric material to yellow. According to one of aspect of the instant invention, doping subsequent to consolidation avoids the exposure of vitamin E to high temperatures and pressures of consolidation and prevents the discoloration of the polymeric material.

25 Doping in the consolidated state also allows one to achieve a gradient of antioxidant in consolidated polymeric material. One can dope a certain thickness surface layer where the oxidation of the polymeric material in a medical device is of concern in terms of wear. This can be achieved by simply dipping or soaking finished devices, for example, a finished medical implant, for example, in pure vitamin E or in a solution of vitamin E at a
30 given temperature and for a given amount of time.

According to the methods described herein, an antioxidant, for example, vitamin E, can be doped into the high-pressure crystallized polymeric material before, during, or after irradiation.

It may be possible that the doped antioxidant can leach out of the polymeric material used in fabrication of medical implants or medical devices either during storage prior to use or during *in vivo* service. For a permanent medical device, the *in vivo* duration can be as long as the remaining life of the patient, which is the length of time between implantation of the device and the death of the patient, for example, 1-120 years. If leaching out of the antioxidant is an issue, the irradiation of the medical implant or medical device or irradiation of any portion thereof can be carried out after doping the antioxidant. This can ensure cross-linking of the antioxidant to the host polymer through covalent bonds and thereby minimize or prevent loss of antioxidant from the medical implant or the device.

According to another aspect of the invention, antioxidant-doped polymeric material or an antioxidant-doped medical implant can be washed in an industrial washer with detergent before packaging and sterilization. An industrial washer, for example, a washer/dryer such as a HAMO T-21 or a washer/disinfectant/dryer such as a HAMO M-100 (HAMO AG, Pieterlen, Switzerland) can be used.

According to another aspect of the invention, antioxidant-doped polymeric material; or an antioxidant-doped medical implant can be soaked in a solvent such as ethanol before packaging and sterilization. A solvent, in which the antioxidant dissolves, is chosen so that the cleaning environment can provide a conducive environment for removing the antioxidant from the polymeric material. This decreases the possibility of antioxidant leaching from the antioxidant-doped polymeric material. The solvent can be at room temperature or at elevated temperatures, under ambient pressure or under elevated pressures, still or stirred. The time for the antioxidant-doped polymeric material or medical implant in contact with the solvent can range from about an hour to at least as long as the time that the doping was done, preferably less than 16 hours.

According to another aspect of the invention, polymeric material, for example, resin powder, flakes, particles, or a mixture thereof, is mixed with an antioxidant and then the mixture is consolidated. The consolidated antioxidant doped polymeric material (blend) can be machined to use as a component in a medical implant or as a medical device.

According to another aspect of the invention, high-pressure crystallized polymeric material, for example, high pressure crystallized resin powder, molded sheet, blown films, tubes, balloons, flakes, particles, or a mixture thereof, can be doped with an antioxidant, for example, vitamin E in the form of α -Tocopherol, by diffusion. High pressure crystallized
5 polymeric material, for example, high pressure crystallized UHMWPE can be soaked in 100% vitamin E or in a solution of α -Tocopherol in an alcohol, for example, ethanol or isopropanol. A solution of α -Tocopherol, about 50% by weight in ethanol can be used to diffuse in to UHMWPE in contact with a supercritical fluid, such as CO₂.

The invention also relates to the following processing steps to fabricate medical
10 devices made out of highly cross-linked polyethylene and containing metallic pieces such as bipolar hip replacements, tibial knee inserts with reinforcing metallic and polyethylene posts, intervertebral disc systems, and for any implant that contains a surface that cannot be readily sterilized by a gas sterilization method.

According to one aspect of the invention, the high pressure crystallized
15 polyethylene component of a medical implant is in close contact with another material (that is a non-modular implant), such as a metallic mesh or back, a non-metallic mesh or back, a tibial tray, a patella tray, or an acetabular shell, wherein the polyethylene, such as resin powder, flakes and particles are directly compression molded to these counter faces. For example, a polyethylene tibial insert is manufactured by compression molding of
20 polyethylene resin powder to a tibial tray, to a metallic mesh or back or to a non-metallic mesh or back. In the latter case, the mesh is shaped to serve as a fixation interface with the bone, through either bony in-growth or the use of an adhesive, such as polymethylmethacrylate (PMMA) bone cement. These shapes are of various forms including, acetabular liner, tibial tray for total or unicompartmental knee implants, patella
25 tray, and glenoid component, ankle, elbow or finger component. Another aspect of the invention relates to mechanical interlocking of the molded polyethylene with the other piece(s), for example, a metallic or a non-metallic piece, that makes up part of the implant. The consolidated polyethylene with metallic piece is then high-pressure crystallized (HPC) to achieve a highly crystalline polyethylene. The HPC can is carried out by either first
30 heating or pressurizing the non-modular implant.

The interface geometry is crucial in that polyethylene assumes the geometry as its consolidated shape. Polyethylene has a remarkable property of 'shape memory' due to its

very high molecular weight that results in a high density of physical entanglements. Following consolidation, plastic deformation introduces a permanent shape change, which attains a preferred high entropy shape when melted. This recovery of the original consolidated shape is due to the 'shape memory', which is achieved when the polyethylene is consolidated. Because of this shape memory, the mechanical interlock will remain intact during and after the high-pressure crystallization of the non-modular implant.

Another aspect of the invention provides that following the high-pressure crystallization of the polyethylene that was molded to the counterface with the mechanical interlock, the hybrid component is irradiated using ionizing radiation to a desired dose level, for example, about 25 kGy to about 1000 kGy, preferably between about 50 kGy and about 150 kGy. Another aspect of the invention discloses that the irradiation step generates residual free radicals and therefore, a melting step is introduced thereafter to quench the residual free radicals followed by another step of high-pressure crystallization. Since the polyethylene is first consolidated into the shape of the interface, thereby setting a 'shape memory' of the polymer, the polyethylene does not separate from the counterface during melting and subsequent high-pressure crystallization step.

In another aspect of the invention, there are provided methods of cross-linking polyethylene, to create a polyethylene-based medical device, wherein the device is immersed in a oxidation-resistant medium such as inert gas or inert fluid, wherein the medium is heated to above the melting point of the irradiated highly crystalline polyethylene, for example, high pressure crystallized UHMWPE (above about 140°C) to eliminate the crystalline matter and to allow the recombination/elimination of the residual free radicals. Because the shape memory of the compression molded polymer is set at the mechanically interlocked interface and that memory is strengthened by the cross-linking step, there is no significant separation at the interface between the polyethylene and the counterface.

Another aspect of the invention provides that following the above steps of free radical elimination, the interface between the metal and the polymer become sterile due to the high irradiation dose level used during irradiation. When there is substantial oxidation on the outside surface of the HPC-polyethylene induced during the free radical elimination step or irradiation step, the device surface can be further machined to remove the oxidized

surface layer. In another aspect, the invention provides that in the case of a post-melting machining of an implant, the melting step can be carried out in the presence of an inert gas.

Another aspect of the invention includes methods of sterilization of the fabricated device, wherein the device is further sterilized with ethylene oxide, gas plasma, or the other
5 gases, when the interface is sterile but the rest of the component is not.

Definitions:

"High pressure crystallized" (HPC) refers to a state of a polymeric material that has undergone high-pressure crystallization process, according to the invention, as described herein.

10 "High-pressure crystallization" refers to a method of making high pressure crystallized polyethylene, according to the invention, as described herein.

The term "highly crystalline" or "high crystallinity" refers to a state of a material of at least about 51% crystallinity.

"Antioxidant" refers to what is known in the art as (see, for example, WO 01/80778,
15 US 6,448,315). Alpha- and delta-tocopherol; propyl, octyl, or decyl gallates; lactic, citric, and tartaric acids and their salts; orthophosphates, tocopherol acetate. Preferably vitamin E.

"Supercritical fluid" refers to what is known in the art, for example, supercritical propane, acetylene, carbon dioxide (CO₂). In this connection the critical temperature is that
20 temperature above which a gas cannot be liquefied by pressure alone. The pressure under which a substance may exist as a gas in equilibrium with the liquid at the critical temperature is the critical pressure. Supercritical fluid condition generally means that the fluid is subjected to such a temperature and such a pressure that a supercritical fluid and thereby a supercritical fluid mixture is obtained, the temperature being above the
25 supercritical temperature, which for CO₂ is 31.3°C, and the pressure being above the supercritical pressure, which for CO₂ is 73.8 bar. More specifically, supercritical condition refers to a condition of a mixture, for example, UHMWPE with an antioxidant, at an elevated temperature and pressure, when a supercritical fluid mixture is formed and then evaporate CO₂ from the mixture, UHMWPE doped with an antioxidant is obtained (see,
30 for example, US 6448315 and WO 02/26464)

The term "compression molding" as referred herein related generally to what is known in the art and specifically relates to high temperature molding polymeric material wherein polymeric material is in any physical state, including powder form, is compressed into a slab form or mold of a medical implant, for example, a tibial insert, an acetabular liner, a glenoid liner, a patella, or an unicompartmental insert.

The term "direct compression molding" as referred herein related generally to what is known in the art and specifically relates to molding applicable in polyethylene-based devices, for example, medical implants wherein polyethylene in any physical state, including powder form, is compressed to solid support, for example, a metallic back, metallic mesh, or metal surface containing grooves, undercuts, or cutouts. The compression molding also includes high temperature compression molding of polyethylene at various states, including resin powder, flakes and particles, to make a component of a medical implant, for example, a tibial insert, an acetabular liner, a glenoid liner, a patella, or an unicompartmental insert, to the counterface.

The term "mechanically interlocked" refers generally to interlocking of polyethylene and the counterface, that are produced by various methods, including compression molding, heat and irradiation, thereby forming an interlocking interface, resulting into a 'shape memory' of the interlocked polyethylene. Components of a device having such an interlocking interface can be referred to as a "hybrid material". Medical implants having such a hybrid material, contain a substantially sterile interface.

The term "substantially sterile" refers to a condition of an object, for example, an interface or a hybrid material or a medical implant containing interface(s), wherein the interface is sufficiently sterile to be medically acceptable, *i.e.*, will not cause an infection or require revision surgery.

"Metallic mesh" refers to a porous metallic surface of various pore sizes, for example, 0.1-3 mm. The porous surface can be obtained through several different methods, for example, sintering of metallic powder with a binder that is subsequently removed to leave behind a porous surface; sintering of short metallic fibers of diameter 0.1-3 mm; or sintering of different size metallic meshes on top of each other to provide an open continuous pore structure.

"Bone cement" refers to what is known in the art as an adhesive used in bonding medical devices to bone. Typically, bone cement is made out of polymethylmethacrylate (PMMA).

5 "High temperature compression molding" refers to the compression molding of polyethylene in any form, for example, resin powder, flakes or particles, to impart new geometry under pressure and temperature. During the high temperature (above the melting point of polyethylene) compression molding, polyethylene is heated to above its melting point, pressurized into a mold of desired shape and allowed to cool down under pressure to maintain a desired shape.

10 "Shape memory" refers to what is known in the art as the property of polyethylene, for example, an UHMWPE, that attains a preferred high entropy shape when melted. The preferred high entropy shape is achieved when the resin powder is consolidated through compression molding.

The phrase "substantially no detectable residual free radicals" refers to a state of a
15 polyethylene component, wherein enough free radicals are eliminated to avoid oxidative degradation, which can be evaluated by electron spin resonance (ESR). The phrase "detectable residual free radicals" refers to the lowest level of free radicals detectable by ESR. The lowest level of free radicals detectable with state-of-the-art instruments is about 10^{14} spins/gram and thus the term "detectable" refers to a detection limit of 10^{14} spins/gram
20 by ESR.

The terms "about" or "approximately" in the context of numerical values and ranges refers to values or ranges that approximate or are close to the recited values or ranges such that the invention can perform as intended, such as having a desired degree of crystallinity or cross-linking and/or a desired lack of free radicals, as is apparent to the skilled person
25 from the teachings contained herein. This is due, at least in part, to the varying properties of polymer compositions. Thus these terms encompass values beyond those resulting from systematic error.

Polymeric Material: Ultra-high molecular weight polyethylene (UHMWPE) refers to linear non-branched chains of ethylene having molecular weights in excess of about
30 500,000, preferably above about 1,000,000, and more preferably above about 2,000,000. Often the molecular weights can reach about 8,000,000 or more. By initial average

molecular weight is meant the average molecular weight of the UHMWPE starting material, prior to any irradiation. See US Patent 5,879,400, PCT/US99/16070, filed on July 16, 1999, PCT/US97/02220, filed February 11, 1997, and US Patent publication 20030149125 (US Application Serial No. 10/252,582), filed September 24, 2002.

5 The products and processes of this invention also apply to various types of polymeric materials, for example, any polyolefin, including high-density-polyethylene, low-density-polyethylene, linear-low-density-polyethylene, ultra-high molecular weight polyethylene (UHMWPE), or mixtures thereof. Polymeric materials, as used herein, also applies to polyethylene of various forms, for example, resin powder, flakes, particles,
10 powder, or a mixture thereof, or a consolidated form derived from any of the above.

 The term "additive" refers to any material that can be added to a base polymer in less than 50 v/v%. This material can be organic or inorganic material with a molecular weight less than that of the base polymer. An additive can impart different properties to the polymeric material, for example, it can be a plasticizing agent, a nucleating agent, or an
15 antioxidant.

 "Blending" generally refers to mixing of a polyolefin in its pre-consolidated form with an additive. If both constituents are solid, blending can be done by using a third component such as a liquid to mediate the mixing of the two components, after which the liquid is removed by evaporating. If the additive is liquid, for example α -tocopherol, then
20 the solid can be mixed with large quantities of liquid, then diluted down to desired concentrations with the solid polymer to obtain uniformity in the blend. In the case where an additive is also an antioxidant, for example vitamin E, or α -tocopherol, then blended polymeric material is also antioxidant-doped. Polymeric material, as used herein, also applies to blends of a polyolefin and a plasticizing agent, for example a blend of UHMWPE
25 resin powder blended with α -tocopherol and consolidated. Polymeric material, as used herein, also applies to blends of an additive, a polyolefin and a plasticizing agent, for example UHMWPE soaked in α -tocopherol.

 "Plasticizing agent" refers to a what is known in the art, a material with a molecular weight less than that of the base polymer, for example α -tocopherol in polyethylene or low
30 molecular weight polybutadiene in polyethylene, in both cases polyethylene being the base polymer. The plasticizing agent is typically added to the base polymer in less than about

20 weight percent. The plasticizing agent increases flexibility and softens the polymeric material.

The term "plasticization" or "plasticizing" refers to the properties that a plasticizing agent imparts on the polymeric material into which it has been added. There properties
5 may include but are not limited to increased elongation at break, reduced stiffness, and increased ductility.

A "nucleating agent" refers to an additive known in the art, an organic or inorganic material with a molecular weight less than that of the base polymer, which increases the rate of crystallization in the polymeric material. Typically, organocarboxylic acid salts, for
10 example calcium carbonate, are good nucleation agents for polyolefins. Also, nucleating agents are typically used in small concentrations such as 0.5 wt%.

Doping: Doping refers to a process well known in the art (see, for example, US Patent Nos. 6,448,315 and 5,827,904). In this connection, doping generally refers to contacting a polymeric material with an antioxidant under certain conditions, as set forth
15 herein, for example, doping UHMWPE with an antioxidant under supercritical conditions. "Doping" also refers to introducing a second component into the base polymeric material in quantities less than 50 v/v%. More specifically, doping refers to introducing an antioxidant into a polymeric material, most often by diffusion of the antioxidant from a surrounding media into the polymeric material. A polymeric material
20 treated in such a way is termed as "antioxidant-doped" polymeric material. However, the process of doping an antioxidant into a polymeric material is not limited to the diffusion process. The polymeric material can be 'doped'; however, by other additives as well, such as a plasticizing agent, in which case the polymeric material treated in such a way may be termed as 'plasticizing agent-doped'.

25 More specifically, for example, HPC polymeric material can be doped with an antioxidant by soaking the material in a solution of the antioxidant. This allows the antioxidant to diffuse into the polymer. For instance, the material can be soaked in 100% antioxidant. The material also can be soaked in an antioxidant solution where a carrier solvent can be used to dilute the antioxidant concentration. To increase the depth of
30 diffusion of the antioxidant, the material can be doped for longer durations, at higher temperatures, at higher pressures, and/or in presence of a supercritical fluid.

The doping process can involve soaking of a polymeric material, medical implant or device with an antioxidant, such as vitamin E, for about an hour up to several days, preferably for about one hour to 24 hours, more preferably for one hour to 16 hours. The antioxidant can be heated to room temperature or up to about 160°C and the doping can be carried out at room temperature or up to about 160°C. Preferably, the antioxidant can be heated to 100°C and the doping is carried out at 100°C.

To further increase the uniformity of antioxidant in the base polymeric material, the doped polymeric material is annealed below or above the melt. The annealing is preferably for about an hour up to several days, more preferably for about one hour to 24 hours, most preferably for one hour to 16 hours. The doped polymeric material can be heated to room temperature or up to about 160°C and the annealing can be carried out at room temperature or up to about 160°C. Preferably, the doped polymeric material can be heated to 100°C and the annealing is carried out at 100°C.

The term "conventional UHMWPE" refers to commercially available polyethylene of molecular weights greater than about 500,000. Preferably, the UHMWPE starting material has an average molecular weight of greater than about 2 million.

By "initial average molecular weight" is meant the average molecular weight of the UHMWPE starting material, prior to any irradiation.

Cross-linking Polymeric Material: Polymeric Materials, for example, UHMWPE can be cross-linked by a variety of approaches, including those employing cross-linking chemicals (such as peroxides and/or silane) and/or irradiation. Preferred approaches for cross-linking employ irradiation. Cross-linked UHMWPE can be obtained according to the teachings of US Patent 5,879,400, PCT/US99/16070, filed on July 16, 1999, PCT/US97/02220, filed February 11, 1997, US Patent Publication 20030149125 (US Application Serial No. 10/252,582), filed September 24, 2002, and US Patent No. 6,641,617, the entirety of which are hereby incorporated by reference.

Consolidated Polymeric Material: Consolidated polymeric material refers to a solid, consolidated bar stock, solid material machined from stock, or semi-solid form of polymeric material derived from any forms as described herein, for example, resin powder, flakes, particles, or a mixture thereof, that can be consolidated. The consolidated polymeric

material also can be in the form of a slab, block, solid bar stock, machined component, film, tube, balloon, pre-form, implant, or finished medical device.

By "crystallinity" is meant the fraction of the polymer that is crystalline. The crystallinity is calculated by knowing the weight of the sample (weight in grams), the heat absorbed by the sample in melting (E, in J/g) and the heat of melting of polyethylene crystals ($\Delta H=291$ J/g), and using the following equation:

$$\% \text{ Crystallinity} = E / w \Delta H$$

By tensile "elastic modulus" is meant the ratio of the nominal stress to corresponding strain for strains as determined using the standard test ASTM 638 M III and the like or their successors.

The term "non-permanent device" refers to what is known in the art as a device that is intended for implantation in the body for a period of time shorter than several months. Some non-permanent devices could be in the body for a few seconds to several minutes, while other may be implanted for days, weeks, or up to several months. Non-permanent devices include catheters, tubing, intravenous tubing, and sutures, for example.

"Permanent device" refers to what is known in the art that is intended for implantation in the body for a period longer than several months. Permanent devices include medical devices, for example, acetabular liner, shoulder glenoid, patellar component, finger joint component, ankle joint component, elbow joint component, wrist joint component, toe joint component, bipolar hip replacements, tibial knee insert, tibial knee inserts with reinforcing metallic and polyethylene posts, intervertebral discs, sutures, tendons, heart valves, stents, and vascular grafts.

"Pharmaceutical compound", as described herein, refers to a drug in the form of a powder, suspension, emulsion, particle, film, cake, or molded form. The drug can be free-standing or incorporated as a component of a medical device.

The term "pressure chamber" refers to a vessel or a chamber in which the interior pressure can be raised to levels above atmospheric pressure.

The term "packaging" refers to the container or containers in which a medical device is packaged and/or shipped. Packaging can include several levels of materials,

including bags, blister packs, heat-shrink packaging, boxes, ampoules, bottles, tubes, trays, or the like or a combination thereof. A single component may be shipped in several individual types of package, for example, the component can be placed in a bag, which in turn is placed in a tray, which in turn is placed in a box. The whole assembly can be sterilized and shipped. The packaging materials include, but not limited to, vegetable parchments, multi-layer polyethylene, Nylon 6, polyethylene terephthalate (PET), and polyvinyl chloride-vinyl acetate copolymer films, polypropylene, polystyrene, and ethylene-vinyl acetate (EVA) copolymers.

The term "heat-shrinkable packaging" refers to plastic films, bags, or tubes that have a high degree of orientation in them. Upon application of heat, the packaging shrinks down as the oriented chains retract, often wrapping tightly around the medical device.

"Melt transition temperature" refers to the lowest temperature at which all the crystalline domains in a material disappear.

"Melting point" refers to the peak melting temperature measured by a differential scanning calorimeter at a heating rate of 10°C per minute when heating from 20°C to 220°C.

Medical implants containing factory-assembled pieces that are in close contact with the polyethylene form interfaces. In most cases, the interfaces are not readily accessible to EtO gas or the GP during a gas sterilization process.

Irradiation: In one aspect of the invention, the type of radiation, preferably ionizing, is used. According to another aspect of the invention, a dose of ionizing radiation ranging from about 25 kGy to about 1000 kGy is used. The radiation dose can be about 50 kGy, about 65 kGy, about 75 kGy, about 100 kGy, about 200 kGy, about 300 kGy, about 400 kGy, about 500 kGy, about 600 kGy, about 700 kGy, about 800 kGy, about 900 kGy, or about 1000 kGy, or above 1000 kGy, or any integer thereabout or therebetween. Preferably, the radiation dose can be between about 50 kGy and about 200 kGy. These types of radiation, including x-ray, gamma and/or electron beam, kills or inactivates bacteria, viruses, or other microbial agents potentially contaminating medical implants, including the interfaces, thereby achieving product sterility. The irradiation, which may be electron or gamma irradiation, in accordance with the present invention can be carried out in air atmosphere containing oxygen, wherein the oxygen concentration in the atmosphere

is at least 1%, 2%, 4%, or up to about 22%, or any integer thereabout or therebetween. In another aspect, the irradiation can be carried out in an inert atmosphere, wherein the atmosphere contains gas selected from the group consisting of nitrogen, argon, helium, neon, or the like, or a combination thereof. The irradiation also can be carried out in a vacuum.

In accordance with a preferred feature of this invention, the irradiation may be carried out in a sensitizing atmosphere. This may comprise a gaseous substance which is of sufficiently small molecular size to diffuse into the polymer and which, on irradiation, acts as a polyfunctional grafting moiety. Examples include substituted or unsubstituted polyunsaturated hydrocarbons; for example, acetylenic hydrocarbons such as acetylene; conjugated or unconjugated olefinic hydrocarbons such as butadiene and (meth)acrylate monomers; sulphur monochloride, with chloro-tri-fluoroethylene (CTFE) or acetylene being particularly preferred. By "gaseous" is meant herein that the sensitizing atmosphere is in the gas phase, either above or below its critical temperature, at the irradiation temperature.

Metal Piece: In accordance with the invention, the piece forming an interface with polymeric material is, for example, a metal. The metal piece in functional relation with polyethylene, according to the present invention, can be made of a cobalt chrome alloy, stainless steel, titanium, titanium alloy or nickel cobalt alloy, for example. Various metal types can also be found in US Serial No. 60/424,709, filed November 8, 2002 (PCT/US03/18053, filed June 10, 2003, WO 2004000159).

Non-metallic Piece: In accordance with the invention, the piece forming an interface with polymeric material is, for example, a non-metal. The non-metal piece in functional relation with polyethylene, according to the present invention, can be made of ceramic material, for example.

Interface: The term "interface" in this invention is defined as the niche in medical devices formed when an implant is in a configuration where a component is in contact with another piece (such as a metallic or a non-metallic component), which forms an interface between the polymer and the metal or another polymeric material. For example, interfaces of polymer-polymer or polymer-metal are in medical prosthesis, such as orthopedic joints and bone replacement parts, for example, hip, knee, elbow or ankle replacements. Various metal/non-metal types and interfaces also can be found in US Serial No. 60/424,709, filed

November 8, 2002 (PCT/US03/18053, filed June 10, 2003, WO 2004000159), the entirety of which is hereby incorporated by reference.

Inert Atmosphere: The term "inert atmosphere" refers to an environment having no more than 1% oxygen and more preferably, an oxidant-free condition that allows free radicals in polymeric materials to form cross links without oxidation during a process of sterilization. An inert atmosphere is used to avoid O₂, which would otherwise oxidize the medical device comprising a polymeric material, such as UHMWPE. Inert atmospheric conditions such as nitrogen, argon, helium, or neon are used for sterilizing polymeric medical implants by ionizing radiation.

Inert atmospheric conditions such as nitrogen, argon, helium, neon, or vacuum are also used for sterilizing interfaces of polymeric-metallic and/or polymeric-polymeric in medical implants by ionizing radiation.

Inert atmospheric conditions also refers to a insert gas, inert fluid, or inert liquid medium, such as nitrogen gas or silicon oil.

Anoxic environment: "Anoxic environment" refers to an environment containing gas, such as nitrogen, with less than 21%-22% oxygen, preferably with less than 2% oxygen. The oxygen concentration in an anoxic environment also can be at least 1%, 2%, 4%, 6%, 8%, 10%, 12%, 14%, 16%, 18%, 20%, or up to about 22%, or any integer thereabout or therebetween.

Vacuum: The term "vacuum" refers to an environment having no appreciable amount of gas, which otherwise would allow free radicals in polymeric materials to form cross links without oxidation during a process of sterilization. A vacuum is used to avoid O₂, which would otherwise oxidize the medical device comprising a polymeric material, such as UHMWPE. A vacuum condition can be used for sterilizing polymeric medical implants by ionizing radiation.

A vacuum condition can be created using a commercially available vacuum pump. A vacuum condition also can be used when sterilizing interfaces of polymeric-metallic and/or polymeric-polymeric in medical implants by ionizing radiation.

Residual Free Radicals: "Residual free radicals" refers to free radicals that are generated when a polymer is exposed to ionizing radiation such as gamma or e-beam irradiation. While some of the free radicals recombine with each other to form crosslinks,

some become trapped in crystalline domains. The trapped free radicals are also known as residual free radicals.

According to one aspect of the invention, the levels of residual free radicals in the polymer generated during an ionizing radiation (such as gamma or electron beam) is preferably determined using electron spin resonance and treated appropriately to reduce the free radicals through recombination.

Sterilization: One aspect of the present invention discloses a process of sterilization of medical implants containing polymeric material, such as cross-linked UHMWPE. The process comprises sterilizing the medical implants by ionizing sterilization with gamma or electron beam radiation, for example, at a dose level ranging from 25-70 kGy, or by gas sterilization with ethylene oxide or gas plasma.

Another aspect of the present invention discloses a process of sterilization of medical implants containing polymeric material, such as cross-linked UHMWPE. The process comprises sterilizing the medical implants by ionizing sterilization with gamma or electron beam radiation, for example, at a dose level ranging from 25-200 kGy. The dose level of sterilization is higher than standard levels used in irradiation. This is to allow cross-linking or further cross-linking of the medical implants during sterilization.

The term "alpha transition" refers to a transitional temperature and is normally around 90-95°C; however, in the presence of a sensitizing environment that dissolves in polyethylene, the alpha transition may be depressed. The alpha transition is believed (An explanation of the "alpha transition temperature" can be found in *Anelastic and Dielectric Effects in Polymeric Solids*, pages 141-143, by N. G. McCrum, B. E. Read and G. Williams; J. Wiley and Sons, N.Y., N.Y., published 1967) to induce motion in the crystalline phase, which is hypothesized to increase the diffusion of the sensitizing environment into this phase and/or release the trapped free radicals. Heating above the alpha transition will also increase the diffusion of the additive, such as plasticizing agent or the antioxidant into the base polymer.

The term "critical temperature" corresponds to the alpha transition of the polyethylene. The term "below melting point" or "below the melt" refers to a temperature below the melting point of a polyethylene, for example, UHMWPE. The term "below melting point" or "below the melt" refers to a temperature less than 155°C, which may vary depending on the

melting temperature of the polyethylene. The term "above melting point" or "above the melt" refers to a temperature above the melting point of a polyethylene, for example, UHMWPE. The term "above melting point" or "above the melt" refers to a temperature more than 145°C, which may vary depending on the melting temperature of the polyethylene. The melting temperature of the polyethylene can be, for example, 155°C, 145°C, 140°C or 135°C, which again depends on the properties of the polyethylene being treated, for example, extended chain crystals, crystallinity, molecular weight averages and ranges, batch variations, etc. For example, "above melting point" or "above the melt" of a polymeric material under high pressure during a high-pressure crystallization process refers to a temperature at or above 150°C. The melting temperature is typically measured using a differential scanning calorimeter (DSC) at a heating rate of 10°C per minute. The peak melting temperature thus measured is referred to as melting point and occurs, for example, at approximately 137°C for some grades of UHMWPE. It may be desirable to conduct a melting study on the starting polyethylene material in order to determine the melting temperature and to decide upon an irradiation and annealing temperature.

The term "annealing" refers to heating the polymer below its peak melting point. Annealing time can be at least 1 minute to several weeks long. In one aspect the annealing time is about 4 hours to about 48 hours, preferably 24 to 48 hours and more preferably about 24 hours. The annealing time required to achieve a desired level of recovery following mechanical deformation is usually longer at lower annealing temperatures. "Annealing temperature" refers to the thermal condition for annealing in accordance with the invention.

The term "contacted" includes physical proximity with or touching such that the sensitizing agent can perform its intended function. Preferably, a polyethylene composition or pre-form is sufficiently contacted such that it is soaked in the sensitizing agent, which ensures that the contact is sufficient. Soaking is defined as placing the sample in a specific environment for a sufficient period of time at an appropriate temperature, for example, soaking the sample in a solution of an antioxidant. The environment is heated to a temperature ranging from room temperature to a temperature below the melting point of the material. The contact period ranges from at least about 1 minute to several weeks and the duration depending on the temperature of the environment.

The term "oxidation-resistant" refers to a state of polymeric material having an oxidation index (A. U.) of less than about 0.5 following aging polymeric materials for 5 weeks in air at 80°C oven. Thus, a oxidation-resistant cross-linked polymeric material generally shows an A. U. of less than about 0.5 after the aging period.

5 "Oxidation index" refers to the extent of oxidation in polymeric material. Oxidation index is calculated by obtaining an infrared spectrum for the polymeric material and analyzing the spectrum to calculate an oxidation index, as the ratio of the areas under the 1740 cm^{-1} carbonyl and 1370 cm^{-1} methylene stretching absorbances after subtracting the corresponding baselines.

10 The term "Mechanical deformation" refers to deformation taking place below the melting point of the material, essentially 'cold-working' the material. The deformation modes include uniaxial, channel flow, uniaxial compression, biaxial compression, oscillatory compression, tension, uniaxial tension, biaxial tension, ultra-sonic oscillation, bending, plane stress compression (channel die) or a combination of any of the above. The
15 deformation could be static or dynamic. The dynamic deformation can be a combination of the deformation modes in small or large amplitude oscillatory fashion. Ultrasonic frequencies can be used. All deformations can be performed in the presence of sensitizing gases and/or at elevated temperatures.

The term "deformed state" refers to a state of the polyethylene material following a
20 deformation process, such as a mechanical deformation, as described herein, at solid or at melt. Following the deformation process, deformed polyethylene at a solid state or at melt is be allowed to solidify / crystallize while still maintains the deformed shape or the newly acquired deformed state.

"IBMA" refers to irradiation below the melt and mechanical annealing. "IBMA"
25 also is referred to as "CIMA" (Cold Irradiation and Mechanically Annealed).

Sonication or ultrasonic at a frequency range between 10 and 100 kHz can be used, with amplitudes on the order of 1-50 microns. The time of sonication is dependent on the frequency and temperature of sonication. In one aspect, sonication or ultrasonic frequency ranged from about 1 second to about one week, preferably about 1 hour to
30 about 48 hours, more preferably about 5 hours to about 24 hours and yet more preferably about 12 hours.

The invention is further described by the following examples, which do not limit the invention in any manner.

EXAMPLES

Example 1. Electron beam irradiation of polyethylene for sterilization or cross-linking.

Blocks or rods of UHMWPE were machined into 1 cm thick pieces. These samples were irradiated using a 2.5 MeV van de Graff generator (e-beam) at Massachusetts Institute of Technology by passing under the electron beam multiple times to achieve the desired radiation dose level (approximately 12.5 kGy per pass).

Example 2. Gamma irradiation of polyethylene for sterilization or cross-linking.

Cylindrical blocks (diameter 89 mm, length larger than 50 cm) were gamma irradiated using a Co⁶⁰ source (Steris Isomedix, Northborough, MA). A group of these blocks were vacuum packaged prior to irradiation and packaged blocks were irradiated. Another group of blocks were packaged and irradiated under nitrogen.

Example 3. Crystallization of polyethylene under high pressure with prior melting (Route 1).

Slab-compression molded GUR 1050 was used. Cylinders (5 cm diameter and 3 cm high) were machined from these blocks and were covered with aluminum, placed in a metal-laminated thermally-sealable pouch. Vacuum was pulled inside the pouch and the pouch was sealed. The vacuum-sealed pouched sample was then placed in a pressure chamber. The samples thus packaged were heated to 180°C in argon, held at 180°C for at least 4 hours, and then isothermally pressurized to 320 MPa (45,000 psi). The pressure was held at about constant for 5 hours. At the completion of the pressurizing cycle, the samples were cooled to room temperature under pressure. Subsequently, the pressure was released.

Example 4. Crystallization of polyethylene under high pressure below the melt (Route 2).

Slab-compression molded GUR 1050 was used. Cylinders (5 cm diameter and 3 cm high) were machined from these blocks and were covered in aluminum, placed in a metal-laminated thermally-sealable pouch. Vacuum was pulled inside the pouch and the pouch was sealed. The vacuum-sealed pouched sample was then placed in a pressure chamber. The samples thus packaged were pressurized to 320 MPa (45,000 psi). Then the temperature was increased to below the melting temperature of the pressurized UHMWPE (180°C) at this pressure and held for 5 hours. The samples were cooled to room temperature under a constant pressure and the pressure was then released.

Example 5. Diffusion of antioxidant into polyethylene.

Slab-compression molded GUR 1050 UHMWPE blocks were machined into thin sections of UHMWPE (thickness=3.2 mm) These samples were placed in contact with α -tocopherol under 0.5 atm of partial nitrogen vacuum at 132°C for 96 hours. Then, the samples were taken out, surfaces cleaned by wiping off antioxidant, and annealed at 132°C under 0.5 atm of partial nitrogen/vacuum for 96 hours.

Example 6. Diffusion of antioxidant into polyethylene subsequent to irradiation (100 kGy).

Slab-compression molded GUR 1050 UHMWPE blocks were gamma irradiated to a dose of 111 kGy in nitrogen. Thin sections of UHMWPE (thickness=3.2 mm) were machined and were placed in contact with α -tocopherol under 0.5 atm of partial nitrogen vacuum at 136°C for 96 hours. Then, the samples were taken out, surfaces cleaned by wiping off antioxidant and annealed at 136°C under 0.5 atm of partial nitrogen/vacuum for 96 hours.

Example 7. Measurement of antioxidant diffusion into polyethylene.

To measure the diffusion profile of the antioxidant in the test samples that were immersed in α -tocopherol (for example, see Examples 5 and 6), a cross-section was cut out of the immersed section (100-150 μ m) using an LKB Sledge Microtome. The thin cross-section was then analyzed using a BioRad UMA 500 infrared microscope (Natick, MA). Infrared spectra were collected with an aperture size of 50x50 μ m as a function of depth away from one of the edges that coincided with the free surface of the sample that contacted the antioxidant during immersion. The absorbance between 1226 and 1295 cm^{-1} is characteristic of α -tocopherol and polyethylene does not absorb near these frequencies. For polyethylene, the 1895 cm^{-1} wave number for the CH_2 rocking mode is a typical choice as an internal reference. The normalized value, which is the ratio of the integrated absorbances of 1260 cm^{-1} and 1895 cm^{-1} , is an index that provides a relative metric of α -tocopherol composition in polyethylene. Figure 3 shows the profile of α -tocopherol polyethylene doped by the procedure described in Example 5 and measured in the manner described in this example.

Example 8. Measurement of oxidation levels in polyethylene.

The oxidation level was quantified as a function of distance away from free surfaces on a number of UHMWPE test samples that were subjected to various processing steps as described in some of the examples below. For this, a thin cross-section (100-150 μ m) of the UHMWPE test sample was cut using a LKB Sledge Microtome. A BioRad UMA 500 infrared microscope was used to measure the extent and depth of oxidation in this section. Infrared spectra were collected with an aperture size of 50x50 μ m as a function of depth away from one of the edges that coincided with the free surface of the sample. The infrared spectra were analyzed to calculate an oxidation index, as the ratio of the areas under the 1740 cm^{-1} carbonyl and 1370 cm^{-1} methylene stretching absorbances.

Example 9. Fatigue crack propagation testing.

The fatigue crack propagation was quantified on a number of UHMWPE test samples that were subjected to various processing steps as described in some of the examples below. For this, fatigue crack propagation testing was performed on a

MiniBionix 858 (MTS, Eden Prairie, MN) following ASTM E-647, the standard method for measurement of fatigue crack growth rates. Compact tension (CT) specimens of Type A1 was used, pre-cracked the notch, and conducted the tests with a stress ratio of 0.1 in a 40°C water bath to simulate the *in vivo* environment.

5

Example 10. Bi-directional Pin-on-Disk (POD) Wear Testing.

The wear rate was quantified on a number of UHMWPE test samples that were subjected to various processing steps as described in some of the examples below. For this, the wear behavior of the UHMWPE sample was tested using cylindrical shaped samples (9 mm diameter and 13 mm height) on a custom-built bi-directional pin-on-disk (POD) wear tester at a frequency of 2Hz. Bovine calf serum was used as lubricant and quantified wear gravimetrically at 0.5 million-cycle intervals. Initially, the pins were subjected to 200,000 cycles of POD testing to remove reach a steady state wear rate independent of diffusion or asperities on the surface. Three pins from each group were tested for a total of 2 million cycles. The wear rate was calculated as the linear regression of wear vs. number of cycles from 0.2 to 2 million cycles.

Example 11. Determination of crystallinity with differential scanning calorimetry.

The crystallinity was quantified on a number of UHMWPE test samples that were subjected to various processing steps as described in some of the examples below. For this, differential scanning calorimetry (DSC) was used to measure the crystallinity of the polyethylene test samples. The DSC specimens were weighed with a Sartorius CP 225D balance to a resolution of 0.01 milligrams and placed in an aluminum sample pan. The pan was crimped with an aluminum cover and placed in a TA instruments Q-1000 Differential Scanning Calorimeter. The samples and the reference were then heated at a heating rate of 10°C/min from -20°C to 180°C, cooled to -10°C and subjected to another heating cycle from -20°C to 180°C at 10°C/min. Heat flow as a function of time and temperature was recorded and the cycles are referred to as 1st heat, 1st cool and 2nd heat, respectively.

Crystallinity was determined by integrating the enthalpy peak from 20°C to 160°C, and normalizing it with the enthalpy of melting of 100% crystalline polyethylene, 291J/g.

Example 12. Crystallinity measurements of polyethylene following high-pressure crystallization by Route 1.

Compression-molded GUR 1050 UHMWPE (also referred as conventional polyethylene) was high pressure-crystallized as described in Example 3. The control samples were compression-molded GUR 1050 UHMWPE without high-pressure crystallization. DSC test samples were prepared from these two types of polyethylenes and were analyzed using a TA Instruments Q-1000 calorimeter as described in Example 11.

The high pressure crystallized samples that were tested contained transparent and opaque sections. When a cross-section was cut out of the cylindrical blocks, the center was most often more transparent than the rim. Figure 4 shows a representative thermogram of the heating cycle of conventional polyethylene with no high-pressure crystallization history and a section from the center of high pressure crystallized conventional polyethylene. The 1st heat crystallinity of the conventional polyethylene was 62% with a peak melting temperature of 134°C. The high pressure crystallized polyethylene showed a 1st heat crystallinity of 78% with the peak melting temperature at 145°C and a shoulder at 130°C.

The high-pressure crystallization parameters used here resulted in an increase in the crystallinity of the conventional polyethylene. In addition, the shift of the peak melting temperature from 134°C to 145°C indicated the formation of larger crystals (extended chain crystals) during high-pressure crystallization.

As discussed above, the high pressure crystallized cylinder of conventional polyethylene radially exhibited a non-uniform appearance (as shown schematically in Figure 5). Variations in the crystallinity with the appearance of the polyethylene are shown in Table 1. A core with a diameter of approximately 2 cm showed high crystallinity. The crystallinity decreased towards the rim. At the opaque rim, the crystallinity was not significantly different from that of conventional polyethylene, which may be due to the pressurization medium (argon gas) diffusing into the outer layer of polyethylene and swelling. The swelling may have resulted in cavitation in polyethylene. Cavitation is known to scatter light and hence, make the polyethylene appear opaque.

Table 1. Crystallinity of conventional polyethylene and high pressure crystallized (HPC) conventional polyethylene.

Material	Crystallinity (%)
Conventional polyethylene	61.8±1.4
HPC conventional polyethylene, transparent	77.7±1.3
HPC conventional polyethylene, opaque	61.3±2.6

Example 13. Crystallinity measurements of previously irradiated and melted polyethylene following high-pressure crystallization by Route 1.

Compression-molded GUR 1050 was e-beam irradiated to 95 kGy at 120°C and subsequently melted (WIAM-95). A cylindrical block (diameter 50 mm, length approximately 40 mm) was high pressure crystallized by Route 1 as described in Example 3.

The WIAM-95 and high-pressure crystallized WIAM-95 were tested using a TA Instruments Q-1000 calorimeter as described in Example 11.

The 1st heat crystallinity was 57% for the WIAM-95 and 62% for the high-pressure crystallized WIAM-95. This increase in the crystallinity was mainly attributed to larger crystals with a peak melting point at 141°C (Figure 6).

The increase in crystallinity and peak melting temperature with high-pressure crystallization was less profound on the irradiated/melted polyethylene compared to conventional polyethylene, as described in Example 12. The decrease in the number of high molecular weight linear chains and the reduction in mobility caused by the cross-linking decreased the rate of crystal growth. Consequently, during high-pressure crystallization in the hexagonal phase crystals did not grow to the same extent in the cross-linked polyethylene as they did in the conventional polyethylene.

These results showed that even at the relatively low pressure of 320 MPa, it is possible to obtain extended chain crystals for both conventional (see Example 12) and highly cross-linked polyethylene. The experiment showed that high-pressure crystallization of both conventional (see Example 12) and highly cross-linked polyethylene led to increases in crystallinity as well as increases in the population of larger crystals compared to conventional GUR 1050 crystallized at ambient pressure.

Example 14. Morphology of transparent and opaque sections on high pressure crystallized samples.

Consolidated GUR 1050 (diameter 50 mm, length 90 mm) block was high pressure crystallized by Route 1, as described in Example 3.

5 A thin cross-section of the block showing both transparent and opaque regions was freeze fractured and gold coated. This cross-section was analyzed on a scanning electron microscope under high vacuum using a field emission gun. Figures 7A, 7B, and 7C show the morphology of the transparent and opaque regions, and the transitional region, respectively.

10 The transparent side showed more uniform morphology with fewer grain boundaries and no cavities, whereas the opaque side showed a high number of grain boundaries and cavities, as seen in Figures 7A and 7B. It is postulated that the cavities are formed by swelling effect of the pressurizing gas (for example, argon gas) used during the high-pressure crystallization. Cavitation is known to scatter light and hence, make the
15 polyethylene appear opaque.

Example 15. Determination of warm irradiation temperature.

Warm irradiation of polyethylene was performed in order to maintain a specific crystalline content during irradiation for high cross-linking. Differential scanning
20 calorimetry (DSC) was used to measure the crystallinity of the polyethylene test samples. The sample and the reference were then heated at a heating rate of 10°C/min from -20°C to 180°C, cooled to -20°C at -10°C/min and subjected to another heating cycle from -20°C to 180°C at 10°C/min. Heat flow as a function of time and temperature was recorded and the cycles are referred to as 1st heat, 1st cool and 2nd heat, respectively.

25 The heat flow was integrated as a function of temperature for the 1st heating cycle of polyethylene from 20°C to 160°C. The integral at each temperature was subtracted from the integral at 160°C and the difference was divided by the theoretical enthalpy of fusion of a 100% crystalline UHMWPE (291 J/mol). In this way, a plot was obtained where percent crystallinity was given as a function of temperature. By using this plot, it was possible to
30 determine the temperature where warm irradiation was to be performed with the desired amount of crystalline content.

Example 16. High pressure crystallized and irradiated (I-HPC) UHMWPE.

GUR 1050 UHMWPE high pressure-crystallized by Route 1, as described in Example 3, was machined into 1 cm thick slices (diameter 5 cm) and electron beam irradiated to a radiation dose of 150 kGy, as described in Example 1, at two different temperatures; room temperature (cold irradiated) (I-HPC1-CI) and at a temperature at which polyethylene was approximately 50% crystalline; in this case, 136°C (warm irradiated) (I-HPC1-WI). The temperature at which the UHMWPE was 50% crystalline was calculated as described in Example 15.

Example 17. High pressure crystallized and irradiated UHMWPE (I-HPC) with subsequent high-pressure crystallization.

UHMWPE prepared as described in Example 16 was further subjected to high-pressure crystallization by Route 1, as described in Example 3.

The crystallinity values for UHMWPE high pressure-crystallized by Route 1 (HPC1), high pressure-crystallized and irradiated (HPC1-CI, HPC1-WI) and high pressure crystallized, cold- or warm-irradiated, and subsequently high pressure-crystallized by Route 1 (HPC1-CI-HPC1 or HPC1-WI-HPC1) samples are shown in Figure 8. Detailed description of the abbreviated processes is shown below in Table 2. Control materials were unirradiated GUR 1050, 100 kGy cold irradiated GUR 1050, 100-kGy cold irradiated and subsequently melted and 95-kGy warm irradiated and subsequently melted UHMWPE.

The HPC1 had 1st heat crystallinity of 79%, which decreased to 78% upon cold-irradiation to a dose of 150 kGy (I-HPC1-CI). The HPC1-CI is expected to contain residual free radicals because of the terminal irradiation step. Therefore, the HPC1-CI was subjected to another step of HPC1. When the HPC1-CI was heated above the melting point prior to pressurization during the second HPC1 step, the residual free radicals would have recombined. However, following the pressurization and crystallization, the crystallinity further decreased to 62% in the final HPC1-CI-HPC1. Nevertheless, the crystallinity of HPC1-CI-HPC1, which has been highly cross-linked and should contain no residual free radicals due to the melting during the high-pressure crystallization process, was still higher

than the crystallinity of both the 100-kGy cold-irradiated and melted sample and the 95-kGy warm irradiated and melted sample.

Table 2. Description of test samples used in high-pressure crystallization and/or irradiation.

Sample ID	Description of process
HPC1	High pressure crystallized through Route 1
HPC1-CI	High pressure crystallized through Route 1, then e-beam irradiated to 150 kGy at room temperature (cold irradiated)
HPC1-WI	High pressure crystallized through Route 1, then e-beam irradiated to 150 kGy at 136°C (warm irradiated)
HPC1-CI-HPC1	High pressure crystallized through Route 1, then e-beam irradiated to 150 kGy at room temperature (cold irradiated) then high pressure crystallized again through Route 1
HPC1-WI-HPC1	High pressure crystallized through Route 1, then e-beam irradiated to 150 kGy at 136°C (warm irradiated), then high pressure crystallized through Route 1

5

Example 18. Cold irradiation with subsequent mechanical deformation.

Two compression molded GUR 1050 rods (diameter 9.1 cm; length 41 cm) were subjected to 100 kGy gamma irradiation in a vacuum package. Both rods were then heated to 130°C and one was subsequently deformed under uniaxial compression normal to its long-axis to a compression ratio of 2.7 (initial diameter/ final diameter). The compression was carried out at 130° C. The compressed rod was held under constant deformation and cooled to room temperature. The load was then released and the dimensions of the rod were recorded (length = 58 cm; width = 16.6 cm; thickness = 40.5 cm). Both the rods were heated to 135°C to recover the residual deformation and the final dimensions were recorded (diameter=7.5 cm; length=40 cm). Thus, one rod was subjected to mechanical deformation and thermal processing, while the other was only subjected to the identical thermal history without deformation to serve as a control.

Example 19. Free radical concentration, oxidation levels, and wear rate of irradiated and mechanically deformed UHMWPE.

Two GUR 1050 blocks, prepared as described in Example 18, were analyzed by using electron spin resonance (ESR) (University of Utah, Department of Physics) to quantify the concentration of residual free radicals. Crystallinity was determined by DSC,

as described in Example 11. Cubes machined from both rods were subjected to accelerated aging at 80°C in air for 5 weeks and the oxidation of the samples was determined by using infrared microscopy, as described in Example 8. Finally, the wear behavior of the mechanically annealed rods (n=3) was determined using our bi-directional wear tester, using a method as described in Example 10.

The ESR analysis showed 2×10^{15} spins/gram for the thermal control, while the mechanically annealed sample showed no detectable residual free radicals, identical to 100 kGy irradiated and melted polyethylene. The DSC analysis showed a crystallinity level of $62 \pm 0.5\%$ for the 1st heat of the mechanically annealed sample, comparable to that of non-irradiated UHMWPE. The crystallinity level typically decreases to 55-57% following post irradiation melting. Accelerated aging led to oxidation in the thermal control (oxidation index = 1.30 ± 0.2), which is significantly more than the mechanically annealed test sample (oxidation index = 0.01 ± 0.01) ($p < 0.01$). The POD wear rate of the mechanically annealed rod was found to be 0.8 ± 0.0 mg/million-cycles, which is comparable to that of 100-kGy irradiated and melted polyethylene.

Example 20. Fatigue crack propagation testing of unirradiated, irradiated and melted samples.

Compression molded UHMWPE GUR 1050 (γ -sterilized in air to 25 kGy-40 kGy), highly cross-linked UHMWPE (γ irradiated in vacuum to 100 kGy), and 100-kGy highly irradiated and melted polyethylene were used as control samples. Gamma irradiation was done as described in Example 2.

Fatigue crack propagation testing was performed as described in Example 9. The stress intensity factor at crack inception (ΔK_i) along with crystallinity values of control samples are shown in Table 3. Crystallinity was determined by DSC as described in Example 11. Crystallinity of UHMWPE was comparable after low and high dose irradiation. When the high dose irradiated polyethylene was melted, crystallinity decreased significantly ($p < 0.001$). The fatigue strength (ΔK_f) decreased by 44% ($p < 0.0001$) when the radiation dose was increased from 25-40 kGy to 100 kGy, presumably due to increased number of cross-links. Melting of the 100-kGy irradiated UHMWPE further decreased the fatigue strength by 19% ($p < 0.001$), presumably due to the decrease in crystallinity.

Table 3: Stress intensity factor range at crack inception of control and irradiated and melted polyethylenes.

Material	25-40-kGy irradiated (no melting)	100-kGy irradiated (no melting)	100-kGy irradiated and melted
Samples tested	3	4	5
ΔK_I (MPa \cdot m ^{1/2})	1.29 \pm 0.04	0.72 \pm 0.04	0.58 \pm 0.03
Crystallinity (%)	62 \pm 1.4	64 \pm 0.9	57 \pm 0.6

5 **Example 21. Fatigue crack propagation testing of high pressure crystallized UHMWPE.**

Fatigue crack propagation testing was performed, as described in Example 9, on compression-molded unirradiated GUR 1050 UHMWPE that was high pressure-crystallized by Route 1 as described in Example 3.

10 The stress intensity factor at crack inception (ΔK_I) was 1.37 \pm 0.06 (n=3) and 1.49 MPa \sqrt m (n=2) for GUR 1050 UHMWPE and high pressure-crystallized GUR 1050 UHMWPE, respectively. We machined the compact tension specimens with crack tip at the core of the high pressure-crystallized cylinder, which, as described in Example 12, was found to be the highly crystalline region.

15

Example 22. Pin-on-disk (POD) wear test of UHMWPE blended with 0.1% and 0.3% Vitamin E prior to consolidation.

An experiment was carried out to determine the effects of Vitamin E blended with UHMWPE resin powder prior to irradiation on the wear resistance of irradiated GUR 1050 UHMWPE. Vitamin E (α -tocopherol) was mixed with GUR 1050 UHMWPE powder, in two concentrations, 0.1 wt% and 0.3 wt%, and consolidated. The consolidation of UHMWPE into blocks was achieved by compression molding. One additional consolidation was carried out without α -tocopherol additive and used as a control. The three consolidated blocks were machined into halves and one half of each was packaged in vacuum and gamma irradiated to 100 kGy, as described in Example 2.

25

Cylindrical pins, 9 mm in diameter and 13 mm in length, were cut out of the irradiated blocks. The pins were first subjected to accelerated aging at 80°C for 5 weeks in

air and subsequently tested on a bi-directional pin-on-disk (POD), as described in Example 10.

The typical wear rate of UHMWPE with no radiation history and no α -tocopherol treatment is around 8.0 milligram per million cycles and for 100-kGy irradiated and melted UHMWPE is 1 mg/MC. The wear rates for the 100-kGy irradiated α -tocopherol blended pins were 2.10 ± 0.17 and 5.01 ± 0.76 milligram per million cycles for the 0.1% and 0.3 wt% α -tocopherol concentration, respectively. The reduction in wear resistance is less with higher α -tocopherol content.

These results suggest that the cross-link density of UHMWPE, achieved by a high irradiation dose, decreases with increasing concentration of α -tocopherol content in the mixture. We believe that this is because of the antioxidant activity of α -tocopherol acting on the free radicals on UHMWPE chains that would in its absence form cross-links with each other.

Example 23. Oxidative stabilization of irradiated UHMWPE by α -tocopherol doping.

Consolidated GUR 1050 UHMWPE bar stock was gamma irradiated to 65 and 100 kGy as described in Example 2. 2 cm cubes were machined of this bar stock. The samples were doped with Vitamin E (α -Tocopherol (α -T)) for 16 hours at room temperature in air. Following doping, the samples were further gamma sterilized at a dose of 27kGy. These two groups are referred to as α -T-92 and α -T-127 with a total radiation dose of 92 kGy and 127 kGy, respectively. The control materials was 100-kGy gamma irradiated GUR 1050.

All samples were accelerated aged at 80°C in air for five weeks. After this, the cubes were cut in halves and oxidation levels were assessed as described in Example 8.

The effects of aging on the oxidation of un-doped and α -T doped samples are shown in Figure 9. The curves represent splined averages of three samples. The 100-kGy irradiated control samples showed significantly higher oxidation levels when compared to α -T-92 and α -T-127 samples; maximum oxidation indices were 3.74 ± 0.16 , 0.48 ± 0.25 ($p < 0.001$), and 0.44 ± 0.06 ($p < 0.001$), respectively. It appeared that α -tocopherol protected irradiated polyethylene against oxidation during accelerated aging at 80° C in air.

Example 24. Oxidative stabilization of high pressure crystallized and irradiated UHMWPE by vitamin E doping.

Compression-molded GUR 1050 (diameter 2") block was high pressure-crystallized, as described in Example 3. The block was machined into thin sections of approximately 8.5 mm thickness. These thin sections were irradiated to a dose of 100-kGy by electron beam, as described in Example 1.

One of the resulting circular sections was cut into four quarters. One was doped in α -tocopherol (vitamin E) for 16 hours at room temperature in air, another was doped in α -tocopherol for 16 hours at 100°C in air. The two corresponding thermal controls were kept at room temperature and at 100°C, respectively, for 16 hours in air without doping. All four samples were cut in halves and one half was accelerated aged in a convection oven for 5 weeks at 80°C in air. The other half was unaged.

The oxidation profiles for all samples were assessed as described in Example 8. There was significant subsurface oxidation in the aged thermal controls while the α -tocopherol doped samples showed significantly lower oxidation levels than controls ($p < 0.01$, and $p < 0.0001$ for room temperature (RT) and 100°C doped samples, see Figures 10 and 11).

Example 25. Oxidative stabilization of high pressure crystallized and irradiated UHMWPE by mechanical deformation.

Compression-molded GUR 1050 (diameter 2") block is high pressure crystallized, as described in Example 3. The block is machined into thin sections of approximately 8.5 mm thickness. These thin sections are irradiated to a dose of 100-kGy by electron beam as described in Example 1.

One thin section is heated to 137°C and mechanically deformed under uniaxial compression at this temperature to a compression ratio of about 2.5 (initial/ final height). The compressed rod is held under constant deformation and cooled back down to room temperature under constant deformation. The load is then released and the dimensions of the rod were recorded. This section is subsequently heated to 144°C to recover the residual

deformation. The thin section is cut in halves and one half was accelerated aged at 80°C in air for 5 weeks.

A thin piece (cross-section approximately 3 mm by 3 mm) is machined out of the remaining piece for electron spin resonance (ESR) analysis (at Department of Physics,
5 University of Memphis, TN).

The high pressure crystallized and 100-kGy irradiated UHMWPE is stabilized by mechanical deformation and ESR values for this sample are not expected to be significantly different than the background number of spins.

Aggressively accelerated aged UHMWPE, which was high pressure crystallized,
10 100-kGy irradiated UHMWPE, and stabilized by mechanical deformation can show significantly less oxidation than that of accelerated aged, high pressure crystallized, and 100-kGy irradiated control.

**Example 26. Pin-on-disk (POD) wear testing of UHMWPE doped with
15 vitamin E after irradiation.**

Consolidated GUR 1050 UHMWPE bar stock was gamma irradiated to 65 and 100 kGy. Cylindrical pins (9 mm diameter, 13 mm length) for POD wear testing were machined from these irradiated polyethylenes. The samples were doped with vitamin E (α -T) for 16 hours at room temperature in air. Following doping, the samples were further
20 gamma sterilized at a dose of 27 kGy. These two groups are referred to as α -T-92 and α -T-127 with a total radiation dose of 92 and 127 kGy, respectively.

Control samples were 1) 100-kGy gamma irradiated GUR 1050 followed by melting at 150°C, 2) 105-kGy gamma irradiated GUR 1050 followed by annealing at 120°C and 3) 25-kGy gamma sterilized GUR 1050 in nitrogen. Gamma irradiation was
25 done as described in Example 2.

Half of the cylindrical samples were subjected to accelerated aging at 80°C in air for five weeks. Both unaged and aged samples were then subjected to POD wear testing, as described in Example 10.

The wear rates of doped and undoped cross-linked and conventional polyethylenes
30 before and after accelerated aging are shown in Figure 12. The wear rate measured for the

two groups of α -T-doped, highly cross-linked polyethylene groups are reported along with the wear rate of 25 kGy irradiated conventional polyethylene (γ -sterilized in nitrogen), 100 kGy irradiated/melted and 105 kGy irradiated/annealed samples before or after aging. The wear rate of the 100 kGy irradiated/annealed and conventional polyethylenes increased after aging. The wear rates of α -T-92 and α -T-127 were equivalent to that of irradiated and melted UHMWPE. Aging did not change the wear behavior of either α -T-92 or α -T-127 ($p > 0.05$). This result indicates that α -T was able to protect UHMWPE against oxidation and since α -T doped samples did not oxidize, their wear rate was similar to unaged specimens.

Example 27. The effect of extraction by ethanol on the oxidation and wear behavior of irradiated UHMWPE.

Consolidated GUR 1050 UHMWPE bar stock was gamma irradiated to 65 kGy and 100 kGy. Cylindrical pins (9 mm diameter, 13 mm length) for POD wear testing and cubes (2 cm) for accelerated aging and oxidation testing were machined from these irradiated polyethylenes. The samples were doped with vitamin E (α -T) for 16 hours at room temperature in air. Following doping, the samples were further gamma sterilized at a dose of 27 kGy. These two groups are referred to as α -T-92 and α -T-127 with a total radiation dose of 92 kGy and 127 kGy, respectively.

Half of the cubes and pins were placed in boiling ethanol overnight to remove α -tocopherol from the UHMWPE. Then, they were placed in a convection oven for 5 weeks in air at 80°C for accelerated aging. The other half were just accelerated aged for 5 weeks at 80°C in air.

Oxidation profiles for the cubes were assessed as described in Example 8 and POD wear testing was done on the pins as described in Example 10. Average maximum oxidation levels observed are as shown in Table 4. There was a significant ($p < 0.05$) but small difference between aged and extracted and aged samples for 100-kGy irradiated control and α -T-127 (Figure 13 and Table 4). Therefore, there was no appreciable difference in oxidation behavior between just aged and extracted and aged samples. Extraction in boiling ethanol did not remove the α -tocopherol from UHMWPE and α -tocopherol was able to protect UHMWPE against oxidation.

Also, the oxidation levels of α -T-92 and α -T-127 were significantly lower than that for the 100-kGy irradiated control for extracted and aged samples. This showed that α -tocopherol was able to protect against oxidation of irradiated UHMWPE after it was subjected to boiling ethanol treatment.

5 **Table 4.** Maximum oxidation values for accelerated aged and ethanol extracted/aged α -tocopherol doped irradiated UHMWPE and 100-kGy irradiated control.

Material	Aged	Ethanol Extracted and Aged
	Oxidation values	
100-kGy control	3.74 \pm 0.16	4.55 \pm 0.33
α -T-92	0.48 \pm 0.25	0.62 \pm 0.14
α -T-127	0.44 \pm 0.06	0.60 \pm 0.08

Similarly, the wear rates of aged α -T-92 and α -T-127 were not affected significantly by the extraction process (see Figure 13).

10

Example 28. The effect of cleaning by washing on the oxidation and wear behavior of irradiated UHMWPE.

Slab compression-molded GUR 1050 UHMWPE blocks (Perplas Ltd., Lancashire, UK) (3" diameter) were gamma-irradiated in vacuum to a dose of 111-kGy (Steris
15 Isomedix, Northborough, MA). These blocks were then machined into half-cubes (2cm \times 2cm \times 1cm).

The half-cubes were immersed in α -tocopherol (α -D,L -tocopherol, Fischer Scientific, Houston, TX) at room temperature and 100°C in air for 1 and 16 hours, respectively (n=3 each). Three thermal controls (room temperature, 100°C for 1 and 16
20 hours) were subjected to the same doping temperature without α -tocopherol.

Cleaning was performed by a portable Kenmore dishwasher (Sears Inc, Hoffman Estates, IL) on normal cycle with rinse and heat drying. During cleaning, all half-cube test samples were placed in a cylindrical nonelastic polyethylene mesh of 2" diameter and closed at the ends. This ensured that the samples did not move around, but the cleaning
25 medium could get through. Electrasol™ (Reckitt Benckiser Inc., Berkshire, UK) was used as cleaning agent.

Oxidation profiles for the cubes were assessed as described in Example 8 and the average of maximum oxidation levels are reported in Table 5.

Table 5. Maximum oxidation values for cleaned and accelerated aged control and α -T doped 111-kGy irradiated UHMWPE. RT denotes that doping was done at room temperature.

Conditions	Average Maximum Oxidation Index
111-kGy RT control	3.68 \pm 0.15
RT 1 hr	0.38 \pm 0.05
RT 16 hrs	0.40 \pm 0.03
111-kGy 100°C 1 hr control	0.97 \pm 0.04
100°C 1 hr	0.098 \pm 0.003
111-kGy 100°C 16 hrs control	0.70 \pm 0.18
100°C 16 hr	0.080 \pm 0.003

These oxidation values for cleaned and aged α -tocopherol-doped 111-kGy irradiated UHMWPE are similar to that of the samples in Example 27 that had been irradiated to 65 and 100-kGy, α -tocopherol doped, and then gamma sterilized (27-kGy) and aged without cleaning; A. U. 0.48 \pm 0.25 and 0.44 \pm 0.06, respectively (Table 4). The cleaning procedure could not to remove the α -tocopherol already diffused through the surface of the UHMWPE.

Thermal control for 111-kGy irradiated, cleaned and aged samples for UHMWPE diffused with α -tocopherol at 100°C for 1 hour showed higher levels of oxidation than that of the α -tocopherol-diffused test samples ($p < 0.0005$). Similarly, thermal control for 111-kGy irradiated, cleaned and aged samples for UHMWPE diffused with α -tocopherol at 100°C for 16 hours showed higher levels of oxidation than that of the α -tocopherol-diffused test samples ($p < 0.0005$). The oxidation levels of the controls and test samples did not show significant difference between a soak time of 1 hour and 16 hours. The oxidation levels for doped samples at 100°C were significantly less than those doped at room temperature ($p < 0.01$ and $p < 0.005$ for 1 and 16 hours, respectively). The oxidation profile of a representative sample of each preparation is shown in Figure 14.

Example 29. Calculating crosslink density of UHMWPE by dynamic mechanical analyzer.

Crosslink density measurements were performed with a dynamic mechanical analyzer (DMA 7e, Perkin Elmer, Wellesley, MA). Rectangular pieces of UHMWPE were set in dental cement and sliced into thin sections (2 mm thick). Small sections were cut out by razor blade from these thin sections to be analyzed (approximately 2 mm by 2 mm). These small pieces were placed under the quartz probe of the DMA and the initial height of the sample was recorded. Then, the probe was immersed in xylene, which was subsequently heated to 130°C and held for 45 minutes. The UHMWPE samples swelled in boiling xylene until equilibrium was reached (the weight change was less than 0.1%). The final weight was recorded.

The crosslink density was calculated in the following manner:

The ratio of the final height to the initial height was cubed to obtain the swell ratio, q , assuming homogeneous expansion in all three directions. Then the crosslink density, ν_c , was calculated from:

$$\nu_c = -\frac{\ln(1-q^{-1}) + q^{-1} + \chi q^{-2}}{\bar{V}_1 q^{-1/3}}$$

where \bar{V}_1 is the partial volume of xylene (136 cm³/mol) and χ is the Flory-Huggins interaction parameter defined as $\chi = 0.33 + 0.55/q$. Average molecular weight between crosslinks was also calculated.

20

$$\bar{M}_c = \frac{\rho}{\nu_c}$$

A more densely cross-linked structure will have higher cross-linking density and lower molecular weight between crosslinks than a more loosely cross-linked structure.

Example 30. Cross-linking density of cold and warm irradiated high pressure crystallized polyethylene.

The crosslink density and molecular weight between crosslinks was calculated as described in Example 29 for I-HPC CI and I-HPC WI to investigate the differences in cross-linking between these two UHMWPEs due to the increased amorphous phase in the warm irradiation process.

Table 6. Crosslink density and molecular weight between crosslinks for warm and cold irradiated previously high pressure crystallized UHMWPEs.

Sample	Crosslink Density (mol/m ³)	Molecular Weight between Crosslinks (g/mol)
I-HPC CI opaque	173±8 (n=3)	4990±230 (n=3)
I-HPC WI opaque	155±31 (n=3)	5711±1042 (n=3)
I-HPC CI transparent	148±36 (n=3)	6075±1670 (n=3)
I-HPC WI transparent	155±13 (n=2)	5580±487 (n=2)

Although the warm and cold irradiated I-HPC polyethylenes did not show significant differences, these 150-kGy irradiated UHMWPEs showed lower cross-linking ratios than 150-kGy cold-irradiated and melted UHMWPE (209 mol/m³; Muratoglu et al., 1999). This is because during irradiation, there was less amorphous phase available in the high pressure crystallized UHMWPE, as discussed in Example 12 (for example, a 78% crystalline UHMWPE will only have 21% amorphous content available for cross-linking as opposed to about 36% for a 100-kGy cold-irradiated UHMWPE). The present approach can provide highly crystalline UHMWPE with a markedly higher degree of cross-linking than previous approaches in the prior art.

Example 31. Vitamin E: Vitamin E (Acros™ 99% D-α-Tocopherol, Fisher Brand), was used in the experiments described herein, unless otherwise specified. The vitamin E used is very light yellow in color and is a viscous fluid at room temperature. Its melting point is 2-3°C.

Example 32. Plasticization of UHMWPE. Compression-molded GUR 1050 UHMWPE was machined into thin sections (diameter approximately 90 mm, thickness 3.2 mm). One thin section was placed in α-tocopherol at 132°C for 5 hours under partial vacuum/nitrogen. Then, it was taken out of the α-tocopherol, the surface was wiped clean with a cotton gauze. The thin section was then placed at 132°C for 48 hours under partial vacuum/nitrogen. α-tocopherol profile in the sample was measured as described in Example 7. The profile was found to be uniform with an average α-tocopherol index of

0.92±0.10 taken from 16 points along the sample thickness. A thin section of consolidated GUR 1050 of the same dimensions was used as control without doping with α -tocopherol.

5 Dogbone specimens (n=5) were stamped out of this thin section and testing was done according to ASTM D-638 Standard test method for tensile properties of plastics at a crosshead speed of 10 mm/min. The engineering strain at break was 521±16% for control UHMWPE and 1107±36% for α -tocopherol-doped and annealed UHMWPE. This result showed that engineering strain at break was significantly increased when UHMWPE was doped uniformly with α -tocopherol. This increase in engineering strain at break may be an indication of the plasticization effect of α -tocopherol on UHMWPE.

10

It is to be understood that the description, specific examples and data, while indicating exemplary embodiments, are given by way of illustration and are not intended to limit the present invention. Various changes and modifications within the present invention will become apparent to the skilled artisan from the discussion, disclosure and data contained herein, and thus are considered part of the invention.

CLAIMS:

1. A method of making a highly crystalline cross-linked polymeric material comprising:
 - a) heating a polymeric material to a temperature above the melt;
 - b) pressurizing the heated polymeric material under at least about 150 MPa;
 - c) holding the polymeric material at this pressure;
 - d) cooling the heated polymeric material to about room temperature;
 - e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; and
 - f) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked polymeric material.
2. A method of making a highly crystalline cross-linked polymeric material comprising:
 - a) pressurizing a polymeric material under at least about 150 MPa;
 - b) heating the pressurized polymeric material to a temperature below the melt of the pressurized polymeric material;
 - c) holding at this pressure and temperature;
 - d) cooling the heated polymeric material to about room temperature;
 - e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material; and
 - f) irradiating the highly crystalline polymeric material at temperature below the melt with ionizing radiation, thereby forming a highly crystalline cross-linked polymeric material.
3. The method of claim 1, wherein the pressurized polymeric material is heated to a temperature about 180°C or about 225°C.
4. The method of claim 2, wherein the pressurized polymeric material is heated to a temperature below 150°C.

5. The method of claim 1 or 2, wherein the highly crystalline polymeric material is irradiated at a temperature between about room temperature and about 90°C.
6. The method of claim 1 or 2, wherein the highly crystalline polymeric material is irradiated at a temperature between about 90°C and the peak melting point of the highly crystalline polymeric material.
7. The method of claim 1 or 2, wherein the polymeric material is pressurized to about 320 MPa.
8. The method of claim 1 or 2 further comprising doping the highly crystalline cross-linked polymeric material with an antioxidant by diffusion, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material.
9. A method of claim 1 further comprising:
 - a) heating a polymeric material to a temperature above the melt;
 - b) pressurizing the heated polymeric material under at least about 150 MPa;
 - c) holding the polymeric material at this pressure;
 - d) cooling the heated polymeric material to about room temperature;
 - e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material cross-linked polymeric material.
10. A method of claim 2 further comprising:
 - a) heating a polymeric material to a temperature below the melt;
 - b) pressurizing the heated polymeric material under at least about 150 MPa;
 - c) holding the polymeric material at this pressure;
 - d) cooling the heated polymeric material to about room temperature;
 - e) releasing the pressure to an atmospheric pressure level, thereby forming a highly crystalline polymeric material cross-linked polymeric material.
11. The method of claim 1, 2, 9, or 10 further comprising:
 - a) doping the highly crystalline cross-linked polymeric material with an antioxidant, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material;

- b) mechanically deforming the polymeric material below its melting point; and
- c) annealing the mechanically deformed polymeric material at a temperature below the melting point, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material containing substantially no detectable residual free radicals.

12. The method of claim 1 or 2 further comprising:

- a) machining the highly crystalline cross-linked polymeric material, thereby forming a medical implant; and
- b) doping the medical implant with an antioxidant by diffusion, thereby forming an antioxidant-doped highly crystalline cross-linked medical implant.

13. The method of claim 1 or 2 further comprising:

- a) doping the highly crystalline cross-linked polymeric material with an antioxidant by diffusion, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material; and
- b) machining the antioxidant-doped highly crystalline cross-linked polymeric material, thereby forming an antioxidant-doped highly crystalline cross-linked medical implant.

14. The method of claim 11, 12, or 13, wherein the antioxidant-doped highly crystalline cross-linked medical implant is packaged and sterilized by ionizing radiation or gas sterilization, thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

15. The method of making oxidation resistant highly crystalline, cross-linked polymeric material comprising:

- a) heating a polymeric material at temperature above the melt;
- b) pressurizing the highly crystalline cross-linked polymeric material under at least about 150 MPa;
- c) holding at this pressure;
- d) cooling the heated polymeric material to room temperature;
- e) releasing the pressure to an atmospheric pressure level;

f) doping the polymeric material with an antioxidant by diffusion, thereby forming an antioxidant-doped polymeric material; and

g) irradiating the antioxidant-doped polymeric material at temperature below the melt with ionizing radiation, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material.

16. The method of making oxidation resistant highly crystalline, cross-linked polymeric material comprising:

a) pressurizing a polymeric material under at least above 150MPa;

b) heating the pressurized polymeric material at temperature below the melt of the pressurized polymeric material;

c) holding at this pressure and temperature;

d) cooling the heated polymeric material to room temperature;

d) releasing the pressure to an atmospheric pressure level;

e) doping the highly crystalline polymeric material with an antioxidant by diffusion, thereby forming an antioxidant-doped highly crystalline polymeric material; and

f) irradiating the antioxidant-doped polymeric material at temperature below the melt with ionizing radiation, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material.

17. The method of claim 15 or 16, wherein the antioxidant-doped highly crystalline cross-linked polymeric material is machined thereby forming a medical implant, this medical implant is packaged and sterilized by ionizing radiation or gas sterilization, thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

18. The method of claim 15 or 16, wherein the antioxidant-doped highly crystalline cross-linked polymeric material is machined thereby forming a medical implant, this medical implant is packaged and sterilized by ionizing radiation or gas sterilization, thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

19. A method of making a antioxidant-doped highly crystalline polymeric material comprising:

a) heating a polymeric material at temperature above the melt;

- b) pressurizing the highly crystalline cross-linked polymeric material under at least about 150 MPa;
- c) holding at this pressure;
- d) cooling the heated polymeric material to room temperature;
- e) releasing the pressure to an atmospheric pressure level;
- f) machining thereby forming a medical implant;
- g) doping the medical implant with an antioxidant by diffusion, thereby forming an antioxidant-doped medical implant; and
- g) irradiating the antioxidant-doped medical implant at temperature below the melt with ionizing radiation, thereby forming an antioxidant-doped highly crystalline cross-linked medical implant.

20. The method of making oxidation resistant highly crystalline, cross-linked polymeric material comprising:

- a) pressurizing a polymeric material under at least above 150MPa;
- b) heating the pressurized polymeric material at temperature below the melt of the pressurized polymeric material;
- c) holding at this pressure and temperature;
- d) cooling the heated polymeric material to room temperature;
- e) releasing the pressure to an atmospheric pressure level;
- f) machining thereby forming a medical implant;
- g) doping the medical implant with an antioxidant by diffusion, thereby forming an antioxidant-doped medical implant; and
- h) irradiating the antioxidant-doped medical implant at temperature below the melt with ionizing radiation, thereby forming an antioxidant-doped highly crystalline cross-linked medical implant.

21. The method of claim 19 or 20, wherein the antioxidant-doped highly crystalline cross-linked medical implant is packaged and sterilized by ionizing radiation or gas sterilization,

thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

22. A method of claim 1 or 2, wherein the polymeric material is a blend of polymer and an additive.

23. The method of claim 22, wherein the highly crystalline cross-linked polymeric material is machined thereby forming a medical implant, this medical implant is packaged and sterilized by ionizing radiation or gas sterilization, thereby forming a sterile and antioxidant-doped highly crystalline cross-linked medical implant.

24. A medical implant comprising the highly crystalline cross-linked polymeric material according to claim 1, 2, 9, 10, 11, 15, or 16.

25. A medical implant comprising the antioxidant-doped highly crystalline cross-linked polymeric material according to claim 19 or 20.

26. The method of claim 12 or 13, wherein the polymeric material is compression molded to another piece or a medical implant, thereby forming an interface or an interlocked hybrid material.

27. The method of claim 11, 12, 13, 15, 16, 19, or 20, wherein the doping is carried out by soaking the medical implant in the antioxidant for about an hour or about 16 hours.

28. The method of claim 1, 2, 9, 10, 12, 13, 15, 16, 19, or 20 further comprising:

- a) mechanically deforming the polymeric material below its melting point; and
- b) annealing the mechanically deformed polymeric material at a temperature below the melting point, thereby forming an antioxidant-doped highly crystalline cross-linked polymeric material containing substantially no detectable residual free radicals.

29. The method of claim 1, 2, 15, 16, 19, or 20, wherein the polymeric material is a polyolefin, a polypropylene, a polyamide, a polyether ketone, or a mixture thereof.

30. The polyolefin of claim 29 is selected from a group consisting of a low-density polyethylene, high-density polyethylene, linear low-density polyethylene, ultra-high molecular weight polyethylene (UHMWPE), or a mixture thereof.

31. The method according to claim 19 or 20, wherein the implant comprises medical devices selected from the group consisting of acetabular liner, shoulder glenoid, patellar component, finger joint component, ankle joint component, elbow joint component, wrist joint component, toe joint component, bipolar hip replacements, tibial knee insert, tibial knee inserts with reinforcing metallic and polyethylene posts, intervertebral discs, sutures, tendons, heart valves, stents, vascular grafts.
32. The method according to claim 1, 2, 15, 16, 19, or 20, wherein the polymeric material is polymeric resin powder, polymeric flakes, polymeric particles, or the like, or a mixture thereof or an additive.
33. The method according to claim 1, 2, 15, 16, 19, or 20, wherein the irradiation is carried out in an atmosphere containing between about 1% and about 22% oxygen.
34. The method according to claim 1, 2, 15, 16, 19, or 20, wherein the irradiation is carried out in an inert atmosphere, wherein the inert atmosphere contains gas selected from the group consisting of nitrogen, argon, helium, neon, or the like, or a combination thereof.
35. The method according to claim 1, 2, 15, 16, 19, or 20, wherein the irradiation is carried out in a vacuum.
36. The method according to claim 1, 2, 15, 16, 19, or 20, wherein the radiation dose is between about 25 and about 1000 kGy.
37. The method according to claim 1, 2, 15, 16, 19, or 20, wherein the radiation dose is about 65 kGy, about 75kGy, or about 150 kGy.
38. The method according to claim 1, 2, 15, 16, 19, or 20, wherein the radiation is a gamma irradiation.
39. The method according to claim 1, 2, 15, 16, 19, or 20, wherein the radiation is an electron beam irradiation.

Abstract

The present invention relates to methods for making highly crystalline cross-linked polymeric material, for example, highly crystalline cross-linked ultra-high molecular weight polyethylene (UHMWPE). The invention also provides methods of making antioxidant-doped highly crystalline cross-linked polymeric material using high pressure and high temperature crystallization processes, medical implants made thereof, and materials used therein.
